FAILURE OF TAMENESS FOR LOCAL COHOMOLOGY

STEVEN DALE CUTKOSKY AND JÜRGEN HERZOG

Abstract. We give an example that shows that not all local cohomology modules
are tame in the sense of Brodmann and Hellus.

Introduction

In their paper “Cohomological patterns of coherent sheaves over projective schemes”,
Brodmann and Hellus [BrHe] raised the following tameness problem: let \( R = \bigoplus_{n \geq 0} R_n \) be a positively graded Noetherian ring such that \( R_0 \) is semilocal, and let \( M \) be a finitely generated graded \( R \)-module. Denote by \( J \) the graded ideal \( \bigoplus_{n > 0} R_n \).

Is true that all the local cohomology modules \( H^i_J(M) \) are tame? The authors call
a graded \( R \)-module \( T \) tame, if there exists an integer \( n_0 \) such that \( T_n = 0 \) for all \( n \leq n_0 \), or else \( T_n \neq 0 \) for all \( n \leq n_0 \).

The tameness problem has been answered in the affirmative in many cases, in par-
ticular, if \( \dim R_0 \leq 2 \). We refer to the article [Br] of Brodmann for a survey on this
problem. In this paper we present an example that shows that the tameness problem
does not always have a positive answer. In our example, \( R_0 \) is a 3-dimensional
normal local ring with isolated singularity.

1. A bigraded ring with periodic local cohomology

Suppose that \( A \) is a very ample line bundle on a projective space \( \mathbb{P}^n \), and \( \mathcal{F} \) is a
coherent sheaf on \( \mathbb{P}^n \). \( \mathcal{F} \) is \( m \)-regular with respect to \( A \) if \( H^i(\mathbb{P}^n, \mathcal{F} \otimes A^\otimes(m-i)) = 0 \)
for all \( i > 0 \).

If \( \mathcal{F} \) is \( m \)-regular with respect to \( A \), then \( H^0(\mathbb{P}^n, \mathcal{F} \otimes A^\otimes k) \) is spanned by
\[
H^0(\mathbb{P}^n, \mathcal{F} \otimes A^\otimes (k-1)) \otimes H^0(\mathbb{P}^n, A)
\]
if \( k > m \) (Lecture 14 [Mu]).

Theorem 1.1. Suppose that \( k \) is an algebraically closed field. Then there exists a
bigraded domain
\[
R = \sum_{m,n \geq 0} R_{m,n} t^m u^n
\]
with the following properties:

1. \( R \) is of finite type over \( R_{0,0} = k \), and is generated in degree 1 over \( R_{0,0} \) (with
respect to the grading \( d(f) = m + n \) for \( f \in R_{m,n} t^m u^n \)).
2. \( R \) has dimension 4, is normal, and the singular locus of \( \text{Spec}(R) \) is the
bigraded maximal ideal \( \sum_{m+n>0} R_{m,n} t^m u^n \).

The first author was partially supported by NSF.
(3) For \( n \geq 0 \), let
\[
R_n = \sum_{m \geq 0} R_{m,n}t^m.
\]

\( R_0 \) is a normal, 3 dimensional graded ring, the \( R_n \) are graded \( R_0 \) modules, and \( R = \sum_{n \geq 0} R_n u^n \) is generated by \( R_1 \) as an \( R_0 \) algebra.

(4) Let \( I = \sum_{m>0} R_{m,n}t^m \) be the graded maximal ideal of \( R_0 \). The singular locus of \( \text{Spec}(R_0) \) is \( I \).

(5) For \( n \geq 0 \), we have
\[
H^2_i(R_n) = \begin{cases} 
k^2 & \text{if } n \text{ is even} \\
0 & \text{if } n \text{ is odd.} \end{cases}
\]

**Proof.** Let \( E \) be an elliptic curve over \( k \), and \( \overline{D} \) be a degree 0 divisor on \( E \) such that \( \overline{D} \) has order 2 in the Jacobian of \( E \) (\( \overline{D} \neq 0 \) and \( 2\overline{D} \sim 0 \)). Let \( p \in E \) be a (closed) point. Let \( S = E \times_k E \), with projections \( \pi_1 : S \to E \) and \( \pi_2 : S \to E \). Let \( H = \pi_2^*(p) + \pi_2^*(\overline{D}) \) be divisors on \( S \). \( H \) and \( D + H \) are ample on \( S \) by the Nakai criterion (Theorem 5.1 [Ha]).

Suppose that \( m, n \in \mathbb{Z} \).

\[
H^1(S, \mathcal{O}_S(mH + nD)) \cong H^0(E, \mathcal{O}_E(mp)) \otimes_k H^1(E, \mathcal{O}_E(mp + n\overline{D})) \oplus H^1(E, \mathcal{O}_E(mp)) \otimes_k H^0(E, \mathcal{O}_E(mp + n\overline{D}))
\]

by the Künneth formula (IV of Lecture 11 [Mu]). If \( m < 0 \), then
\[
H^0(E, \mathcal{O}_E(mp)) = 0 \text{ and } H^0(E, \mathcal{O}_E(mp + n\overline{D})) = 0.
\]

If \( m > 0 \), then by Serre duality,
\[
H^1(E, \mathcal{O}_E(mp)) \cong H^0(E, \mathcal{O}_E(-mp)) = 0
\]
and
\[
H^1(E, \mathcal{O}_E(mp + n\overline{D})) \cong H^0(E, \mathcal{O}_E(-mp - n\overline{D})) = 0.
\]

If \( m = 0 \), we have
\[
H^1(S, \mathcal{O}_S(nD)) \cong H^1(E, \mathcal{O}_E(n\overline{D})) \oplus H^0(E, \mathcal{O}_E(n\overline{D})).
\]

By the Riemann-Roch theorem on \( E \), we have for \( m, n \in \mathbb{Z} \),
\[
h^1(S, \mathcal{O}_S(mH + nD)) = \begin{cases} 
2 & \text{if } m = 0 \text{ and } n \text{ is even} \\
0 & \text{otherwise.}
\end{cases}
\]

Let \( \mathcal{E} = \mathcal{O}_S \oplus \mathcal{O}_S(D) \). Let \( X = \mathbb{P}(\mathcal{E}) \) be the projective space bundle ([Ha, Section II.7]) with projection \( \pi : X \to S \) and associated line bundle \( \mathcal{O}_X(1) \). Since \( H \) is ample on \( S \), there exists a number \( \tau \) such that \( \pi^* \mathcal{O}_S(nH) \otimes \mathcal{O}_X \mathcal{O}_X(1) \) is very ample on \( X \) for all \( n \geq \tau \) ([Ha, Proposition II.7.10 and Exercise II.5.12(b)])

There exists \( l \geq \tau \) such that \( lH \) and \( D + lH \sim l(D + H) \) are very ample.

There exists an odd number \( r_2 > 0 \) such that \( H^i(S, \mathcal{O}_S((r_2 - i)(D + aH))) = 0 \) for all \( a \geq 1 \) and \( i > 0 \). Thus for all \( a \geq 1 \), \( \mathcal{O}_S \) is \( r_2 \) regular for \( D + aH \). It follows that \( H^0(S, \mathcal{O}_S(2r_2(D + aH))) \) is spanned by \( H^0(S, \mathcal{O}_S(D + aH))^{\otimes m} \) for all \( a \geq 1 \) and \( m \geq 1 \).

2
There exists $r_1 > 0$ such that $\mathcal{O}_S$ and $\mathcal{O}_S(D)$ are $r_1$ regular for $lH$. Thus $\mathcal{O}_S(nD)$ is $r_1$ regular for $lH$ for all $n \in \mathbb{Z}$ (since $2D \sim 0$).

Choose $a > r_1$. For $m, n \geq 0$, $H^0(S, \mathcal{O}_S(mr_2(D + aH) + nr_2alH))$ is spanned by $H^0(S, \mathcal{O}_S(mr_2(D + aH))) \otimes H^0(S, \mathcal{O}_S(r_2alH))^{\otimes n}$ since $\mathcal{O}_S(mr_2D)$ is $r_1$ regular for $lH$.

Thus $H^0(S, \mathcal{O}_S(mr_2(D + aH) + nr_2alH))$ is spanned by

$$H^0(S, \mathcal{O}_S(r_2(D + aH)))^{\otimes m} \otimes H^0(S, \mathcal{O}_S(r_2alH))^{\otimes n}.$$ 

Let $R_{m,n} = H^0(S, \mathcal{O}_S(mr_2alH + nr_2(D + alH)))$.

Let

$$R_n = \sum_{m \geq 0} R_{m,n} t^m,$$

$$R = \sum_{m,n \geq 0} R_{m,n} t^m u^n = \sum_{n \geq 0} R_n u^n,$$

where $t, u$ are indeterminates. $R$ is normal (by [Z, Theorem 4.2]). By our construction, $R$ is generated as an $R_{0,0} = k$ algebra by $R_{1,0}t$ and $R_{0,1}u$. We deduce that $R$ is standard graded as an $R_0$ algebra, $R_0$ is normal and standard graded as an $R_{0,0} = k$ algebra. We have an isomorphism $S \cong \text{Proj}(R_0)$, with associated line bundle $\mathcal{O}_S(1) \cong \mathcal{O}_S(r_2alH)$. Since $S$ is nonsingular, the singular locus of Spec($R_0$) is the graded maximal ideal $I = \sum_{m > 0} R_{m,0} t^m$ of $R_0$. The sheafication of the module $R_n$ on $S$ is

$$\tilde{R}_n = \mathcal{O}_S(nr_2(D + alH)),$$

by Exercise II.5.9 (c) [Ha]. For $n \geq 0$, by (1), and the exact sequences relating local cohomology and global cohomology ([E, A.4.1]), we have

$$H^2_\ell(R_n) \cong \oplus_{m \in \mathbb{Z}} H^1(S, \mathcal{O}_S(mr_2alH + nr_2(D + alH))) \cong H^1(S, \mathcal{O}_S(nr_2D)).$$

Thus

$$H^2_\ell(R_n) \cong \begin{cases} k^2 & \text{if } n \text{ is even,} \\ 0 & \text{if } n \text{ is odd.} \end{cases}$$

Let $\mathcal{L} = \pi^*\mathcal{O}_S(r_2alH) \otimes_{\mathcal{O}_X} \mathcal{O}_X(1)$. By our choice of $l$, $\mathcal{L}$ is very ample on $X$. For $r \geq 0$, we have (by [Ha, Proposition II.7.11])

$$H^0(X, \mathcal{L}^r) \cong H^0(S, \text{Sym}^r(\mathcal{E}) \otimes_{\mathcal{O}_S} \mathcal{O}_S(rr_2alH))$$

$$\cong \oplus_{n=0}^r H^0(S, \mathcal{O}_S(rr_2alH + nD))$$

$$\cong \oplus_{n=0}^r H^0(S, \mathcal{O}_S((r_2alH + nr_2D))) \quad \text{since } r_2 \text{ is odd and } D \text{ has order } 2$$

$$\cong \oplus_{n=0}^r H^0(S, \mathcal{O}_S((r - n)r_2alH + nr_2(D + alH)))$$

$$\cong \sum_{m+n=r} R_{m,n} t^m u^n.$$ 

Thus $R$, with the above grading, is the coordinate ring of $X$, with respect to an embedding in projective space given by $H^0(X, \mathcal{L})$. Since $X$ is nonsingular, the singular locus of Spec($R$) is the bigraded maximal ideal $\sum_{m+n>0} R_{m,n} t^m u^n$ of $R$. \qed
Choose a surjective homomorphism $S_0 \to R_0$ of graded $k$-algebras, where $S_0$ is a polynomial ring of dimension $d$. Then the graded version of the local duality theorem ([BH, Theorem 3.6.19]) and property (5) of $R$ imply that

$$\text{Ext}^{d-2}_{S_0}(R_n, S_0) \cong \begin{cases} k^2 & \text{if } n \text{ is even}, \\ 0 & \text{if } n \text{ is odd}. \end{cases}$$

More generally, if $R$ is a positively graded Noetherian $R_0$-algebra, $M$ is a finitely generated graded $R$-module, and $N$ an $R_0$-module, one could ask whether the graded $R$-modules $\text{Ext}^i_{R_0} (M, N)$, $\text{Ext}^i_{R_0} (N, M)$ and $\text{Tor}^i_{R_0} (M, N)$ behave tamely. The above example shows that this is in general not the case for $\text{Ext}^i_{R_0} (M, N)$, while for the other two functors this is the case. In fact, computing $\text{Ext}^i_{R_0} (N, M)$ and $\text{Tor}^i_{R_0} (M, N)$ by using a graded minimal free $R_0$-resolution of $N$, these two homology groups are subquotients of a complex whose chains are a finite number of copies of $M$. Hence $\text{Ext}^i_{R_0} (N, M)$ and $\text{Tor}^i_{R_0} (M, N)$ are finitely generated graded $R$-modules. Say, $n_0$ is the highest degree of a generator of $\text{Ext}^i_{R_0} (N, M)$. Then one has

$$\text{Ext}^i_{R_0} (N, M_n) = 0 \text{ for all } n \geq n_0, \quad \text{or else } \text{Ext}^i_{R_0} (N, M_n) \neq 0 \text{ for all } n \geq n_0.$$ 

The same holds true for $\text{Tor}^i_{R_0} (M, N)$.

2. An example of a non-tame cohomology module

In this section we use the result of the previous section to produce an example which gives a negative answer to the tameness problem [BrHe, Problem 5.1] of Brodmann and Hellus. The construction is based on a duality theorem for bigraded modules which is given in [HR].

Let $k$ be a field, $S = k[x_1, \ldots, x_r, y_1, \ldots, y_s]$ the standard bigraded polynomial ring. In other words, we set $\deg x_i = (1, 0)$ and $\deg y_j = (0, 1)$ for all $i, j$. We denote by $P_0 = (x_1, \ldots, x_r)$ the graded maximal ideal of $k[x_1, \ldots, x_r]$ and by $Q_0 = (y_1, \ldots, y_s)$ the graded maximal ideal of $k[y_1, \ldots, y_s]$, and set $P = P_0 S$, $Q = Q_0 S$ and $S_+ = P + Q$.

Let $M$ be a finitely generated bigraded $S$-module. We set $M_j = \bigoplus_{i \in \mathbb{Z}} M_{(i,j)}$. Then $M = \bigoplus_{j \in \mathbb{Z}} M_j$, where each $M_j$ is a finitely generated graded $k[x_1, \ldots, x_r]$-module.

We denote by $M^\vee$ the bigraded $k$-dual of $M$, i.e. the bigraded $k$-module with components

$$(M^\vee)_{(i,j)} = \text{Hom}_k(M_{(-i,-j)}, k) \quad \text{for all } i, j.$$ 

By the local duality theorem one has natural isomorphisms of bigraded $S$-modules

$$H^i_{S_+} (M) \cong \text{Ext}^{r+s-i} (M, S(-r,-s)) \quad \text{for all } i.$$

In particular, all the modules $H^i_{S_+} (M)^\vee$ are finitely generated bigraded $S$-modules, see [BH, Theorem 3.6.19] for a similar statement in the graded case.

We shall use the following result [HR, Proposition 2.5]

**Proposition 2.1.** Suppose $M$ is a finitely generated graded generalized Cohen-Macaulay $S$-module of dimension $d$ (i.e. $M$ is Cohen-Macaulay on the punctured spectrum of $S$, or equivalently, $H^i_{S_+} (M)$ has finite length for $i < d$). We let $N$ be
the finitely generated bigraded \(S\)-module \(H^4_{S_+}(M)^\vee\). Then one has the following long exact sequence of bigraded \(S\)-modules

\[ 0 \to H^1_P(N) \to H^{d-1}_Q(M)^\vee \to H^{d-1}_P(N) \to H^d_Q(M)^\vee \to H^{d-2}_S(M)^\vee \to \cdots \]

Note that \((H^d_{S_+}(M)^\vee)_j = 0\) for \(i > 0\) and all \(j \gg 0\). Thus the long exact sequence of Proposition 2.1 yields the following isomorphisms

\[(H^{d-i}_Q(M)^\vee) \cong (H^{d-i}_Q(M)^\vee)_j \cong H^i_P(N)_j \cong H^i_{P_0}(N_j)\]

for all \(i > 0\) and all \(j \gg 0\).

Now let \(R\) be the bigraded \(k\)-algebra of Theorem 1.1. We choose a bigraded presentation \(S \to R\) with \(S = k[x_1, \ldots, x_r, y_1, \ldots, y_s]\), and view \(R\) a bigraded \(S\)-module.

We have dim \(R = 4\), so that \(\omega_R = H^4_{S_+}(R)^\vee\) is the canonical module of \(R\). Since \(R\) is a domain, the canonical module localizes, that is, we have \((\omega_R)_\varnothing \cong \omega_{R_\varnothing}\) for all \(\varnothing \in \text{Spec}(R)\), see for example [HK, Korollar 5.25]. Furthermore, since the singular locus of \(R\) is the bigraded maximal ideal \(m\) of \(R\), it follows that \(R_\varnothing\) is regular for all \(\varnothing \neq m\). In particular, \((\omega_R)_\varnothing \cong R_\varnothing\) is Cohen-Macaulay for all \(\varnothing \neq m\). This shows that \(\omega_R\) is a generalized Cohen-Macaulay module. Finally, since \(R\) is normal, \(R\) is in particular \(S_2\), and this, by a result of Aoyama [A, Proposition 2], implies that \(R \cong H^4_{S_+}(\omega_R)^\vee\). Thus if we set \(J = QR = \bigoplus_{n>0} R_n\), then (3) applied to \(\omega_R\) yields

\[(H^2_J(\omega_R)^\vee) \cong H^2_J(R_j)\quad \text{for} \quad j \gg 0.\]

Thus in view of property (5) of \(R\) we obtain

**Corollary 2.2.** For all \(j \ll 0\) one has

\[ H^2_J(\omega_R)_j \cong \begin{cases} k^2 & \text{if } j \text{ is even} \\ 0 & \text{if } j \text{ is odd}. \end{cases} \]

Localizing at the graded maximal ideal of \(R_0\) we may as well assume that \(R_0\) is local and obtain the same result.
