DICHOTOMY AND FREDHOLM PROPERTIES OF EVOLUTION EQUATIONS

YURI LATUSHKIN, ALIN POGAN, AND ROLAND SCHNAUBELT

ABSTRACT. Under minimal assumptions, we characterize the Fredholmity and compute the Fredholm index of abstract differential operators \(-d/dt + A(\cdot)\) acting on spaces of functions \(f : \mathbb{R} \to X\). Here \(A(t)\) are (in general) unbounded operators on the Banach space \(X\) and our results are formulated in terms of exponential dichotomies on two halflines for the propagator solving the evolution equation \(\dot{u}(t) = A(t)u(t)\) in a mild sense.

1. INTRODUCTION

In this paper we obtain the final version of the infinite dimensional Dichotomy Theorem for well–posed differential equations

\[
(Gu)(t) := -u'(t) + A(t)u(t) = f(t), \quad t \in \mathbb{R},
\]

on a Banach space \(X\). Our main Dichotomy Theorem 1.1 characterizes the Fredholm property of the (closure of the) operator \(G\) on, say, \(L^p(\mathbb{R}, X)\) and determines its Fredholm index in terms of the exponential dichotomies on half lines of the propagator solving (1.1). The linear operators \(A(t), t \in \mathbb{R}\), on \(X\) are unbounded, in general, and we only require that the corresponding initial value problem (1.3) below is well–posed in a mild sense. We reduce the problem to the study of a weighted shift operator on \(X\)–valued sequence spaces, and give a purely operator theoretical proof of our Theorem 1.1 based on the discrete version of the “input-output” method from the theory of differential equations.

The Dichotomy Theorem is related to problems arising from finite dimensional dynamics, Morse theory, and the theory of travelling waves. For a detailed discussion concerning these connections, we refer to [12, Section 7]. This theorem can further be viewed as an extension of a simple form of the celebrated Atiyah–Patodi–Singer Index Theorem, cf. [22].

For finite dimensional \(X = \mathbb{C}^d\), versions of the Dichotomy Theorem were established in the papers [6], [17], [18], and [23]. Here \(A(t)\) are matrices and \(G = -d/dt + A(\cdot)\) is defined on the Sobolev space \(W^{1,p}(\mathbb{R}, \mathbb{C}^d)\), for instance. In this case \(G\) is Fredholm if and only if the propagator (or evolution family) \(\{U(t, \tau)\}_{t \geq \tau}\) solving

\[
\frac{d}{dt}U(t, \tau) = A(t)U(t, \tau), \quad U(\tau, \tau) = I,
\]

on \(\mathbb{R}\) is a bounded reversible evolution family. The fundamental result in the finite dimensional setting is due to Aizenman and Simon [6] and a proof can be found in [23, Section 7].
(1.1) has exponential dichotomies on $\mathbb{R}_-$ and $\mathbb{R}_+$. However, applications to partial differential equations require an infinite dimensional version of the Dichotomy Theorem for unbounded $A(t)$. Progresses in this direction have been made in [2], [3], [4], [5], [9], [10], [12], [13], [19], [20], [21], [24], and the references therein. We stress that the proofs of the finite and infinite dimensional versions of the Dichotomy Theorem are quite different due to many new difficulties arising in the infinite dimensional setting, as described in Sections 1 and 7 of [12].

Recently, several authors discussed the Fredholmity of the operator $G$ and related questions (such as perturbation results) in specific infinite dimensional settings. In [20] and [21] a differential equation of the form (1.1) on a Banach space $X$ having the UMD property was studied, where the constant domain of the operators $A(t)$ is compactly embedded in $X$ and $A(t) \rightarrow A_\pm$ as $t \rightarrow \pm \infty$. Assuming that the spectra of $A_\pm$ do not intersect $i\mathbb{R}$, it was proved that $G$ is Fredholm on $L^p(\mathbb{R}, X)$ for $p \in (1, \infty)$, and its index was computed in terms of the spectral flow of $A(\cdot)$. (Here the Cauchy problem (1.3) could be ill-posed.) In [9] and [10] theorems of this type are established for general (well-posed) parabolic problems. The latter approach is based on a detailed study of the maximal regularity property of the solutions to the (inhomogeneous) differential equation. The case of bounded operators $A(t)$ was considered in [1] in connection with applications to infinite dimensional theory. In [19] and [24] necessary and sufficient conditions for the Fredholmity of $G$ were given for a special class of infinite dimensional differential equations having a backward uniqueness property, cf. (BU) below. This work is related to a detailed study of travelling waves for elliptic problems on cylinders. All these papers dealt with the asymptotically autonomous case (except for [19]) and imposed restrictive regularity hypotheses ensuring the closedness of $G = -\frac{d}{dt} + A(\cdot)$ defined on $\text{dom}(\frac{d}{dt}) \cap \text{dom}(A(\cdot))$. See [9], [10], [12] for more details.

In a different line of research, one starts with a general evolution family $U(t, \tau)$, $t \geq \tau$, and constructs an operator $G$ on, say, $L^p(\mathbb{R}, X)$ as described below. There are no additional restrictions on the regularity or the asymptotic behaviour of $A(\cdot)$. If (1.3) is well-posed in a classical sense, then $G$ is the closure of $G = -\frac{d}{dt} + A(\cdot)$. In [5] (see also [2, 3, 4]) it was further assumed a priori that $U(t, \tau)$ has exponential dichotomies on semi-lines. Then a ‘node operator’ was introduced, and it was proved that $G$ and the node operator are Fredholm at the same time with equal indices. On the other hand, the authors in [12] required $X$ to be reflexive and imposed a condition of backward uniqueness on the evolution family. Under these hypotheses, they could characterize the Fredholmity of $G$ as we do below. In the current paper we discard any additional assumption and establish the following theorem (the relevant definitions are given in Section 2).

**Theorem 1.1.** Assume that $U = \{U(t, \tau) : t \geq \tau; t, \tau \in \mathbb{R}\}$ is a strongly continuous, exponentially bounded evolution family on a Banach space $X$, and let $G$ be the generator of the associated evolution semigroup defined on $E(\mathbb{R}) = L^p(\mathbb{R}, X)$, $p \in [1, \infty)$, or on $E(\mathbb{R}) = C_0(\mathbb{R}, X)$. Then the operator $G$ is Fredholm if and only if there exist real numbers $a \leq b$ such that the following two conditions hold:

(i) The evolution family $U$ has exponential dichotomies with the family of projections $\{P^-_a\}_{t \leq a}$ and $\{P^+_b\}_{t \geq b}$ on $(-\infty, a]$ and $[b, \infty)$, respectively.

(ii) The node operator $N(b, a)$, acting from $\ker P^-_a$ to $\ker P^+_b$ and defined by the rule $N(b, a) = (I - P^+_b)U(b, a)|_{\ker P^-_a}$, is Fredholm.
Moreover, if $G$ is Fredholm, then we have the equalities $\dim \ker G = \dim \ker N(b, a)$, $\text{codim} \im G = \text{codim} \im N(b, a)$, and $\ind G = \ind N(b, a)$. In particular, the Fredholm properties of $G$ are independent of the choice of the function space $E(\mathbb{R})$.

In Proposition 6.1 we further give a description of the range of $G$, in the spirit of the classical Fredholm alternative using the adjoint evolution family.

The evolution semigroup $T = \{T(t)\}_{t \geq 0}$ mentioned in Theorem 1.1 is defined on $L^p(\mathbb{R}, X)$, $p \in [1, \infty)$, or on $C_0(\mathbb{R}, X)$ by the formula $(T(t)f)(\tau) = U(\tau, \tau-t)f(\tau-t)$, $\tau \in \mathbb{R}$, $t \geq 0$, see [2], [7], [25]. This is a strongly continuous semigroup, and we denote its generator by $G$. The operator $G$ can be described in terms of mild solutions to an inhomogeneous evolution equation, as shown by the following lemma, see [7, Proposition 4.32].

**Lemma 1.2.** A function $u$ belongs to the domain $\text{dom} G$ of the operator $G$ on $L^p(\mathbb{R}, X)$, $p \in [1, \infty)$, resp., on $C_0(\mathbb{R}, X)$, if and only if $u \in L^p(\mathbb{R}, X) \cap C_0(\mathbb{R}, X)$, resp., $u \in C_0(\mathbb{R}, X)$, and there exists an $f \in L^p(\mathbb{R}, X)$, resp., $f \in C_0(\mathbb{R}, X)$, with

$$u(t) = U(t, \tau)u(\tau) - \int_\tau^t U(t, \sigma)f(\sigma)d\sigma \quad \text{for all } t \geq \tau \text{ in } \mathbb{R}. \quad (1.2)$$

If (1.2) holds, then $Gu = f$.

Suppose for a moment that the differential equation

$$u'(t) = A(t)u(t), \quad t \geq \tau, \quad u(\tau) = x \in \text{dom}(A(\tau)), \quad (1.3)$$

is well-posed in a classical sense, i.e., the operators $A(t)$ are all densely defined and there is an evolution family $U$ such that $U(t, \tau)\text{dom}(A(\tau)) \subseteq \text{dom}(A(t))$ for $t \geq \tau$ and $u(t) = U(t, \tau)x$ is the unique $C^1$-solution of (1.3). Then $G$ is the closure of the operator $G = -\frac{d}{dt} + A(\cdot)$ on $L^p(\mathbb{R}, X)$, $p \in [1, \infty)$, resp., on $C_0(\mathbb{R}, X)$, with the domain $\text{dom} G = \{u \in W^{1,p}(\mathbb{R}, X) : u(t) \in \text{dom}(A(\cdot)) \text{ a.e.}, A(\cdot)u(\cdot) \in L^p(\mathbb{R}, X)\}$, resp. $\{u \in C_0(\mathbb{R}, X) : u(t) \in \text{dom}(A(t)) \text{ for } t \in \mathbb{R}, u'(\cdot), A(\cdot)u(\cdot) \in C_0(\mathbb{R}, X)\}$, where $W^{1,p}(\mathbb{R}, X)$, $p \in [1, \infty)$, is the usual Sobolev space, cf. [7, Theorem 3.12]. However, one knows only rather restrictive assumptions on the operators $A(t)$ implying well-posedness in the above sense, and almost no necessary conditions, see the survey given in [25]. Thus we only assume that the evolution family $U$ exists, without any reference to operators $A(t)$.

Our Theorem 1.1 was shown in [12, Theorem 1.1] assuming in addition that $X$ is reflexive and $U$ has the following backward uniqueness property (BU).

**(BU.1):** If $u \in C_0(\mathbb{R}, X)$, $u(t) = U(t, \tau)u(\tau)$ for all $t \geq \tau$ in $\mathbb{R}$, and $u(\tau) = 0$ for some $\tau \in \mathbb{R}$, then $u = 0$.

**(BU.2):** If $v \in C_b^{w,\ast}(\mathbb{R}, X^\ast)$, $v(\tau) = U(t, \tau)^\ast v(t)$ for all $t \geq \tau$ in $\mathbb{R}$, and $v(\tau) = 0$ for some $\tau \in \mathbb{R}$, then $v = 0$.

(See also Remark 7.4.) We point out that these properties do not hold for certain evolution families solving parabolic partial differential equations. Some sufficient conditions for (BU) are known for specific classes of partial differential equations. However, in general it is rather difficult to verify (BU), cf. [9] and references therein.

In Section 7 we present two examples, where $G$ is Fredholm but (BU) fails.

Our proof also shows that if $U$ does satisfy the backward uniqueness property (BU), then we can take $a = b = 0$ in our Theorem 1.1, see Proposition 7.1. Using a different method, this result was proved in [12, Theorem 1.2] for reflexive $X$. As
shown in Example 7.3, the conclusion of Theorem 1.1 with \( a = b = 0 \) is false in general if (BU) is violated.

The proof of the (simpler) ‘if’ part of Theorem 1.1 given in [12] or [2, 3, 4, 5] works without the reflexivity assumption and without the backward uniqueness property. The main objective of the current paper is to remove these additional conditions in the proof of the ‘only if’ part. Without these hypotheses the problem at hand becomes significantly more involved, and thus the methods used in the current paper are quite different from those in [12]. We use an approach going back to Daletskii and Krein, [8], and Levitan and Zhikov, [14], which is sometimes called the “input-output method.”

In [8] this technique was used to characterize the exponential stability of an evolution family \( U \). The basic idea is to solve the equation \( Gu = f \) on \( \mathbb{R}^+ \) for functions of the form \( f(t) = \varphi'(t)U(t,s)x \) (where \( \varphi \) is a suitable scalar function). For such \( f \) it can be seen that \( u(t) = -\varphi(t)U(t,s)x \) using a version of Lemma 1.2. If \( G \) is invertible on \( \mathbb{R}^+ \), one can then deduce the required exponential estimate by means of the boundedness of \( G^{-1} \). A variant of this argument shows that the stable and unstable subspaces of \( U \) yield a time depending decomposition of \( X \) if \( G \) is invertible on \( \mathbb{R} \), leading to a characterization of exponential dichotomy on \( \mathbb{R} \) given in [14]. In the more recent contributions [15] and [16], this approach was employed to characterize exponential dichotomy on \( \mathbb{R}^+ \). Here additional difficulties appear at the initial time \( t = 0 \) which correspond to the fact that the dichotomy projections are not unique in the half line case, in general. We point out that the input–output method is quite different from the approach used in [2], [3], [4], and [7] (and its modifications in [5] and [12]), where the main tool for the construction of the exponential dichotomy, say, on \( \mathbb{R} \) was the Riesz projection of the semigroup generated by \( G \).

In the present paper we deal with operators \( G \) being Fredholm. This fact forces us to ‘delete’ the kernel and co–kernel of \( G \). Moreover, we can only expect to obtain exponential dichotomies of \( U \) on (possibly disjoint) semi-lines \((-\infty, a] \) and \([b, \infty) \), see Example 7.3. Thus we must control the behaviour of \( U(t,s) \) at \( a \), \( b \), and in between. In order to achieve this, we first discretize the problem (see Section 2). In Section 3, we then treat the stable subspaces on \( \mathbb{Z}^+ \) and the unstable subspaces on \( \mathbb{Z}^- \). These spaces are somewhat easier to handle since they are given explicitly in terms of \( U \), see (3.1) and (3.2). The main difficulty is the construction of the correct complements of these spaces. Here we need several decompositions of \( X \) given in Lemma 3.6. In Sections 4 and 5 we construct the dichotomies on \( [b, \infty) \) and \((-\infty, a] \) by propagating the “traces” of the kernel and co-kernel of \( G \) at the points \( b \) and \( a \) (Lemmas 4.2 and 5.2). In Section 6 we deal with the node operator to show condition (ii) in Theorem 1.1, and the formulas for the defect numbers. In Section 7 we describe the backward uniqueness properties in terms of the traces of the kernel and co-kernel of \( G \), and show that one can take \( a = b = 0 \) in Theorem 1.1 when the backward uniqueness properties hold, see Proposition 7.1.

2. Notation, definitions, and preliminary results

We set \( \mathbb{R}^+ = \{ t \in \mathbb{R} : t \geq 0 \} \), \( \mathbb{R}^- = \{ t \in \mathbb{R} : t \leq 0 \} \), \( \mathbb{Z}^+ = \{ n \in \mathbb{Z} : n \geq 0 \} \), \( \mathbb{Z}^- = \{ n \in \mathbb{Z} : n \leq 0 \} \), and we use \( t, \tau, \sigma \) to denote real numbers and \( n, m, k, j \) to denote integers. We write \( c \) for a generic (positive) constant. \( A^*, \text{dom}(A), \ker A, \text{im} A \) are the adjoint, the domain, the kernel and the range of an operator \( A \) on a
Banach space $X$ with dual space $X^*$, and $A_\lambda$ is the restriction of $A$ on the subspace $Y$ of $X$. The set of all bounded linear operators from a Banach space $X$ to a Banach space $Y$ is designated by $B(X,Y)$, and $B(X) = B(X,X)$. For a subspace $Y \subseteq X^*$, we use the (non-standard!) notation $Y^\perp = \{ x \in X : \langle x, \xi \rangle = 0 \text{ for all } \xi \in Y \}$ for the annihilator, where $\langle \cdot, \cdot \rangle$ is the $\langle X, X^* \rangle$-pairing. If $P$ and $Q$ are two projections on $X$, then $X = \text{im}P \oplus \ker P = \text{im}Q \oplus \ker Q$, where throughout $\oplus$ denotes a decomposition of a Banach space into closed subspaces with trivial intersection.

With respect to these decompositions, each $A \in B(X)$ can be written as the $2 \times 2$ operator matrix

$$A = \begin{bmatrix} PAQ & PA(I-Q) \\ (I-P)AQ & (I-P)A(I-Q) \end{bmatrix}.$$ 

$C_0(\mathbb{R}, X)$ is the space of continuous functions $f : \mathbb{R} \to X$ vanishing at $\pm \infty$; $C_b^{\infty}(\mathbb{R}, X^*)$ is the space of bounded, weak star continuous functions $f : \mathbb{R} \to X^*$; $L^p(\mathbb{R}, X)$ is the space of (equivalence classes of) Bochner $p$-integrable functions $f : \mathbb{R} \to X$, where $p \in [1, \infty)$. We denote by $\chi_M$ the characteristic function of a set $M$. If $\{\varphi_k\}_{k \in \mathbb{Z}}$ is a numerical sequence and $x \in X$, then $\varphi \otimes x$ denotes the $X$-valued sequence $\{\varphi_k x\}_{k \in \mathbb{Z}}$.

An evolution family $\mathcal{U} = \{ U(t, \tau) \}_{t \geq \tau}$ on a set $J \subset \mathbb{R}$ is a family of operators $U(t, \tau) \in B(X)$, $t \geq \tau$, $\tau, \sigma \in J$, satisfying

$$U(t, \tau)U(\tau, \sigma) = U(t, \sigma) \quad \text{for all } t \geq \tau \geq \sigma \quad \text{with } t, \tau, \sigma \in J.$$

It is called strongly continuous if the map $(t, \tau) \mapsto U(t, \tau)x$ is continuous for all $x \in X$ and $t \geq \tau$ in $J$. If $\|U(t, \tau)\| \leq M e^{\omega (t-\tau)}$ for some constants $M \geq 1$ and $\omega \in \mathbb{R}$ and all $t \geq \tau$ in $J$, then $\mathcal{U}$ is exponentially bounded.

Definition ED. An evolution family $\mathcal{U}$ has an exponential dichotomy on $J \subset \mathbb{R}$ if there exist closed subspaces $\{X_s(t)\}_{t \in J}$ and $\{X_u(t)\}_{t \in J}$ of $X$ such that

(i) $X = X_s(t) \oplus X_u(t)$ for all $t \in J$ and $U(t, \tau)X_s(\tau) \subseteq X_s(t)$, $U(t, \tau)X_u(\tau) \subseteq X_u(t)$ for all $t \geq \tau$ in $J$;

(ii) $U(t, \tau)X_s(\tau)$ is an invertible from $X_u(\tau)$ to $X_u(t)$ for all $t \geq \tau$ in $J$;

(iii) there are constants $N, \nu > 0$ such that

$$\|U(t, \tau)X_u(\tau)\| \leq Ne^{-\nu(t-\tau)}, \quad \|U(t, \tau)X_s(\tau)\|^{-1} \leq Ne^{-\nu(t-\tau)} \quad \text{for all } t \geq \tau \text{ in } J.$$

We denote by $P_t$ the projection onto $X_s(t)$ parallel to $X_u(t)$. If $J = [b, \infty)$ or $J = \mathbb{Z} \cap [b, \infty)$ we write $X^+_s(t)$ and $P^+_t$ for the respective dichotomy subspaces and the dichotomy projections, and if $J = (-\infty, a]$ or $J = \mathbb{Z} \cap (-\infty, a]$ we write $X^-_s(t)$ and $P^-$ for the respective dichotomy subspaces and the dichotomy projections. If $\mathcal{U}$ is strongly continuous and exponentially bounded on an unbounded interval $J$ and $(i), (iii)$ hold, then the function $t \mapsto P_t$ is strongly continuous and uniformly bounded on $J$, see [8, Lemma IV.1.1, IV.3.2] or [15, Lemma 4.2].

In order to prove Theorem 1.1, we pass from continuous time to discrete time; i.e., we replace the operator $G$ in the statement of Theorem 1.1 by the difference operator $D$ defined by the formula

$$D(x_n)_{n \in \mathbb{Z}} = (x_n - U(n, n-1)x_{n-1})_{n \in \mathbb{Z}}, \quad (2.1)$$

cf. [3], [7], [11]. The operator $D$ is acting on the sequence space $\mathcal{E}(\mathbb{Z})$, where $\mathcal{E}(\mathbb{Z}) = \ell^p(\mathbb{Z}, X)$ if $\mathcal{E}(\mathbb{R}) = L^p(\mathbb{R}, X)$, $p \in [1, \infty)$ and $\mathcal{E}(\mathbb{Z}) = C_0(\mathbb{Z}, X)$ if $\mathcal{E}(\mathbb{R}) = C_0(\mathbb{R}, X)$. This replacement is possible due to Theorem 1.4 and Lemma 1.5 of [12] (cf. also [11, Thm.7.6.5], [3, Thm.1], [4, Thm.2]). These results say that $\mathcal{U}$
has an exponential dichotomy on $\mathbb{R}_+$ if it has an exponential dichotomy on $\mathbb{Z}_+$ and that $\text{im } G$ is closed if and only if $\text{im } D$ is closed, $\dim \ker G = \dim \ker D$, and $\text{codim im } G = \text{codim im } D$. In particular, the operator $G$ is Fredholm if and only if $D$ is Fredholm, and $\text{ind } G = \text{ind } D$. Since we focus our attention on the proof of the ‘only if’ part of Theorem 1.1, throughout Sections 2–5 we will assume that $D$ is a Fredholm operator.

In the following we collect some basic properties of the spaces

$$X_n = \{ x \in X : \exists (x_k)_{k \in \mathbb{Z}} \in \ker D \text{ so that } x = x_n \} \quad \text{and} \quad (2.2)$$

$$X_{n,*} = \{ \xi \in X^* : \exists (\xi_k)_{k \in \mathbb{Z}} \in \ker D^* \text{ so that } \xi = \xi_n \}, \quad (2.3)$$

where $n \in \mathbb{Z}$. Simple computations show that

$$D^*(\xi_n)_{n \in \mathbb{Z}} = (\xi_n - U(n+1,n)^*\xi_{n+1})_{n \in \mathbb{Z}},$$

$$\ker D = \{ (x_n)_{n \in \mathbb{Z}} \in \mathcal{E}(\mathbb{Z}) : x_n = U(n,m)x_m \text{ for all } n \geq m \} \quad (2.4)$$

$$\ker D^* = \{ (\xi_n)_{n \in \mathbb{Z}} \in \mathcal{E}(\mathbb{Z})^* : \xi_m = U(n,m)^*\xi_n \text{ for all } n \geq m \}. \quad (2.5)$$

These formulas imply that $U(n,m)X_m = X_n$ and $U(n,m)^*X_{n,*} = X_{m,*}$ for all $n \geq m$. Because of these identities and the Fredholm property of $D$, we obtain $0 \leq \dim X_{n+1} \leq \dim X_n \leq \dim \ker D < \infty$ and $0 \leq \dim X_{n,*} \leq \dim X_{n+1,*} \leq \dim \ker D^* < \infty$ for all $n \in \mathbb{Z}$. Hence, there are $a, b \in \mathbb{Z}$ with $a \leq b$ such that $\dim X_n$ and $\dim X_{n,*}$ are constant for $n \leq a$ and $n \geq b$.

Without loss of generality, we may assume that $a = 0$ and $b \geq 1$ due to the following translation argument: For $a \in \mathbb{Z}$, consider the strongly continuous evolution family $U_a$ defined by $U_a(t, \tau) = U(t + a, \tau + a)$ for $t \geq \tau$ in $\mathbb{R}$, and the shift operator $S_a$ on $\mathcal{E}(\mathbb{Z})$ acting by $S_a(x_n)_{n \in \mathbb{Z}} = (x_{n+a})_{n \in \mathbb{Z}}$. If $D_a$ is the difference operator associated to $U_a$ as in (2.1), then $D_a = S_a D S_a^{-1}$, and thus $D_a$ and $D$ have the same Fredholm properties. So, choosing an appropriate $a$, we have that $\dim X_n(U_a)$ and $\dim X_{n,*}(U_a)$ are constant for $n \leq 0$. To sum things up, we impose the following assumption, without loss of generality.

**Hypothesis 1.** $U$ is a discrete, exponentially bounded evolution family on $\mathbb{Z}$, $D$ is a Fredholm operator, and $\dim X_n$ and $\dim X_{n,*}$ are constant for $n \geq b$, $n \leq 0$, and some $1 \leq b \in \mathbb{Z}$.

**Lemma 2.1.** Let Hypothesis 1 be satisfied. Then $\dim X_n \leq \dim \ker D < \infty$ and $\dim X_{n,*} \leq \dim \ker D^* < \infty$ for $n \in \mathbb{Z}$ and the following assertions hold.

(i) $U(n,m)X_m = X_n$ for all $n \geq m$;

(ii) $U(n,m)^*X_{n,*} = X_{m,*}$ for all $n \geq m$;

(iii) $U(n,m)|_{X_m} : X_m \to X_n$ is invertible if $m \leq n \leq 0$ or $n \geq m \geq b$;

(iv) $U(n,m)^*|_{X_{n,*}} : X_{n,*} \to X_{m,*}$ is invertible if $m \leq n \leq 0$ or $n \geq m \geq b$;

(v) $X_n \subseteq X_{n,*}^+$ for all $n \in \mathbb{Z}$;

(vi) $x \in X_{m,*}^+$ if and only if $U(n,m)x \in X_{n,*}^+$, where $n \geq m$ in $\mathbb{Z}$.

**Proof.** We already observed after (2.4) and (2.5) that the first assertion and statements (i) and (ii) hold. Assertions (iii) and (iv) follow from these assertions and Hypothesis 1. In order to show (v), take $x = (x_k)_{k \in \mathbb{Z}} \in \ker D$, $\xi = (\xi_k)_{k \in \mathbb{Z}} \in \ker D^*$, and $n \in \mathbb{Z}$. Then (2.5) and (2.4) imply that

$$\langle x_n, \xi_n \rangle = \langle x_n, U(k,n)^*\xi_k \rangle = \langle U(k,n)x_n, \xi_k \rangle = \langle x_k, \xi_k \rangle$$
for all $k \geq n$. Letting $k \to \infty$, we deduce $\langle x_n, \xi_n \rangle = 0$ since $x \in c_0(\mathbb{Z}, X)$ and $\xi$ is bounded. Thus assertion (v) holds. The last assertion follows from the identities

$$\langle x, \xi_n \rangle = \langle x, U(n, m)^*\xi_n \rangle = \langle U(n, m)x, \xi_n \rangle$$

for all $n \geq m$ and all $\xi = (\xi_n)_{n \in \mathbb{Z}} \in \ker D^*$.

Since $X_0 \subseteq X^\perp_{0,\ast}$ and $\dim X_0 < \infty$, we can choose a closed subspace $X'_0$ of $X$ with

$$X^\perp_{0,\ast} = X_0 \oplus X'_0$$

(2.6)

Moreover, we define the following closed subspaces of $\mathcal{E}(\mathbb{Z})$ and $\mathcal{E}(\mathbb{Z})^*$

$$\mathcal{F} = \{x = (x_n)_{n \in \mathbb{Z}} \in \mathcal{E}(\mathbb{Z}) : x_n \in X^\perp_{n,\ast} \text{ for all } n \in \mathbb{Z}\},$$

(2.7)

$$\mathcal{F}_0 = \{x = (x_n)_{n \in \mathbb{Z}} \in \mathcal{F} : x_0 \in X'_0\},$$

(2.8)

$$\mathcal{F}_{b,\ast} = \{\xi = (\xi_n)_{n \in \mathbb{Z}} \in \mathcal{E}(\mathbb{Z})^* : \xi_n \in X_{n,\ast} \text{ for all } n \in \mathbb{Z}, \xi_b = 0\}.$$

(2.9)

On these spaces the operators $D_0 := D|\mathcal{F}_0$ and $D_{b,\ast} := D^*|\mathcal{F}_{b,\ast}$ have better properties than $D$ and $D^*$, respectively, as stated in the next lemma.

**Lemma 2.2.** Let Hypothesis 1 be satisfied. Then the following assertions hold.

(i) $\mathcal{F}$ is $D$-invariant and $D|\mathcal{F} : \mathcal{F} \to \mathcal{F}$ is surjective.

(ii) The operator $D_0 = D|\mathcal{F}_0 : \mathcal{F}_0 \to \mathcal{F}$ is invertible;

(iii) $D_{b,\ast} = D^*|\mathcal{F}_{b,\ast}$ is uniformly injective, that is, $\|D_{b,\ast}\xi\|_{\mathcal{E}(\mathbb{Z})^*} \geq c\|\xi\|_{\mathcal{E}(\mathbb{Z})^*}$ for all $\xi \in \mathcal{F}_{b,\ast}$ and a constant $c > 0$.

**Proof.** Assertions (i) and (ii) can be shown exactly as [12, Lemma 2.2] and [12, Lemma 2.3], respectively. To prove (iii), we have to verify that $D_{b,\ast}$ is injective and has closed range. If $\xi = (\xi_n)_{n \in \mathbb{Z}} \in \ker D_{b,\ast}$ then $\xi_n$ is closed and $D_{b,\ast}$ is injective. Next, take $\eta = \lim_{n \to \infty} D_{b,\ast}\xi_n$ with $\xi_n \in \mathcal{F}_{b,\ast}$. Since $D^*$ is Fredholm, $\im D^*$ is closed and thus there is $\zeta \in \mathcal{E}(\mathbb{Z})^*$ with $\eta = D^*\zeta$. Moreover, there exist an operator $D^1 \in B(\mathcal{E}(\mathbb{Z})^*)$ and a finite rank operator $R$ such that $D^1D^* = I + R$ and $\im R \subseteq \ker D^*$. Observe that $D^*(\zeta - \xi_n) \to 0$ as $n \to \infty$. Then it follows that $\zeta - \xi_n + w_n \to 0$ as $n \to \infty$ for $w_n = R(\zeta - \xi_n) \in \ker D^*$. Passing to the elements of the sequences, we deduce that $\zeta_k = \lim_{n \to \infty} (\xi_{k,n} - w_{k,n}) \in X_{k,\ast}$ for each $k \in \mathbb{Z}$, where $\zeta = (\xi_k)_{k \in \mathbb{Z}}$, $\xi_n = (\xi_{k,n})_{k \in \mathbb{Z}}$, and $w_n = (w_{k,n})_{k \in \mathbb{Z}}$. There is a vector $\theta = (\theta_k)_{k \in \mathbb{Z}} \in \ker D^*$ with $\xi_b = \theta_b$ by (2.3). Hence, $\zeta - \theta \in \mathcal{F}_{b,\ast}$ by (2.9) and $\eta = D(\zeta - \theta) = D_{b,\ast}(\zeta - \theta)$. So the range of $D_{b,\ast}$ is closed. \hfill $\square$

**Lemma 2.3.** Let $V$ be a subspace of $X$, $\{\xi_1, \ldots, \xi_d\}$ be a set of linearly independent vectors in $X^*$, and $Y_* = \text{Span}\{\xi_1, \ldots, \xi_d\}$. Then the following assertions hold.

(i) There are $x_1, \ldots, x_d \in X$ such that $\langle x_i, \xi_j \rangle = \delta_{ij}$ for all $i, j \in \{1, \ldots, d\}$, where $\delta_{ij}$ is the Kronecker Delta.

(ii) Let $v_1, \ldots, v_d \in V$ satisfy $\langle v_i, \xi_j \rangle = \delta_{ij}$ for all $i, j \in \{1, \ldots, d\}$ and set $W = \text{Span}\{v_1, \ldots, v_d\}$. Then $V = (V \cap Y_*^\perp) \oplus W$.

(iii) $\text{codim} Y_*^\perp = d < \infty$.

**Proof.** (i) It is clear that assertion (i) holds if $d = 1$. Assume that it is true for some $d \in \mathbb{N}$ and let $\{\xi_1, \ldots, \xi_d, \xi_{d+1}\}$ be a system of linearly independent vectors.
We want to prove by contradiction that
\[ \bigcap_{i=1}^{d} \ker \xi_i \nsubseteq \ker \xi_{d+1}. \] (2.10)

Take \( x \in X \) and let \( \{x_1, \ldots, x_d\} \) satisfy the induction hypothesis. If (2.10) were false, then we would obtain
\[ x - \sum_{j=1}^{d} \langle x, \xi_j \rangle x_j \in \bigcap_{i=1}^{d} \ker \xi_i \subseteq \ker \xi_{d+1}, \quad \text{i.e., } \xi_{d+1} = \sum_{j=1}^{d} \langle x, \xi_{d+1} \rangle \xi_j. \]

This is a contradiction, and so (2.10) is true. Thus there exists \( x_{d+1} \in \bigcap_{i=1}^{d} \ker \xi_i \) with \( \langle x_{d+1}, \xi_{d+1} \rangle = 1 \), concluding the proof of (i).

(ii) Let \( x \in V \) and set \( y = x - \sum_{j=1}^{d} \langle x, \xi_j \rangle v_j \in V \). Then
\[ \langle y, \xi_i \rangle = \langle x, \xi_i \rangle - \sum_{j=1}^{d} \langle x, \xi_j \rangle \delta_{ji} = 0 \]
for all \( i \in \{1, \ldots, d\} \). As a consequence, \( y \in V \cap Y_{+}^d \) and so \( x \in (V \cap Y_{+}^d) + W \). We have shown that \( V \subseteq (V \cap Y_{+}^d) + W \). The converse inclusion follows directly from \( W \subseteq V \). If \( x \in (V \cap Y_{+}^d) \cap W \), then there are \( \lambda_1, \ldots, \lambda_d \in \mathbb{C} \) such that \( x = \sum_{j=1}^{d} \lambda_j v_j \). Therefore
\[ \lambda_i = \sum_{j=1}^{d} \lambda_j \delta_{ji} = \sum_{j=1}^{d} \langle \lambda_j v_j, \xi_i \rangle = \langle x, \xi_i \rangle = 0 \]
for all \( i \in \{1, \ldots, d\} \), and hence \( (V \cap Y_{+}^d) \cap W = \{0\} \). Thus (ii) holds.

(iii) The third assertion follows from (i) and (ii).

\[ \square \]

Lemma 2.4. Let \((a_n)_{n \in \mathbb{Z}^+}\) be a sequence of positive numbers and \((b_n)_{n \in \mathbb{Z}^+} \in c_0(\mathbb{Z}^+, \mathbb{R}^+)\) such that \(a_{m+n} \leq b_n a_m\), for all \(n, m \in \mathbb{Z}^+\). Then there are \(N, \nu > 0\), depending only on \((b_n)_{n \in \mathbb{Z}^+}\) such that \(a_{n+m} \leq N e^{-\nu n} a_m\) for all \(n, m \in \mathbb{Z}^+\).

Proof. Take \(n_0 \in \mathbb{Z}^+\) such that \(b_{n_0} < e^{-1}\). We set \(N = e^{\max\{b_{n_0}, \ldots, b_{n_0} + 1\}}\), \(\nu = 1/n_0\), and \(p = \left[\frac{\nu}{n_0}\right]\) for \(n, m \in \mathbb{Z}^+\). Then we obtain
\[ a_{n+m} \leq b_{n-pn_0} a_{pn_0+m} \leq \frac{N}{e^{p}} a_{pn_0+m} \leq \frac{N}{e} (b_{n_0})^p a_m \leq N e^{-\nu n_0} a_m = N e^{-\nu n_0} a_m. \]

\[ \square \]

3. Dichotomy estimates on the stable subspaces of \(\mathbb{Z}^+\) and the unstable subspaces on \(\mathbb{Z}^\)\)

In this section we will use the notations \(\mathcal{E}(\mathbb{Z}_\pm) = \ell^p(\mathbb{Z}_\pm, X)\) if \(\mathcal{E}(\mathbb{Z}) = \ell^p(\mathbb{Z}, X)\), \(p \in [1, \infty)\), and \(\mathcal{E}(\mathbb{Z}_\pm) = c_0(\mathbb{Z}_\pm, X)\) if \(\mathcal{E}(\mathbb{Z}) = c_0(\mathbb{Z}, X)\). We introduce the stable and unstable subspaces of \(U\) on \(\mathbb{Z}^+\) and \(\mathbb{Z}^-\), respectively, by
\[ X^+_u(k) = \{x \in X : \langle U(n+k, k)x, n \in \mathbb{Z}^+ \rangle \in \mathcal{E}(\mathbb{Z}_+)\}, \quad k \geq 0, \quad (3.1) \]
\[ X^-_u(k) = \{x \in X : \exists(x_n)_{n \in \mathbb{Z}^-} \in \mathcal{E}(\mathbb{Z}_-)\text{ with } x_n = U(n, m)x_m \text{ for } m \leq n \leq 0 \text{ and } x_k = x\}, \quad k \leq 0. \quad (3.2) \]
We observe that
\[ U(n,m)X^+_s(m) \subseteq X^+_s(n) \quad \text{for all } n \geq m \geq 0, \]  
\[ U(n,m)X^-_u(m) = X^-_u(n) \quad \text{for all } m \leq n \leq 0. \]  
Let \( U^+_s(n,m) : X^+_s(m) \to X^+_s(n) \) and \( U^-_u(n,m) : X^-_u(m) \to X^-_u(n) \) be the linear operators defined by \( U^+_s(n,m)x = U(n,m)x \) for \( n \geq m \geq 0 \) and \( x \in X^+_s(m) \) and by \( U^-_u(n,m)x = U(n,m)x \) for \( m \leq n \leq 0 \) and \( x \in X^-_u(m) \). The following lemma shows in particular that the above subspaces do not match at \( n = 0 \), in general.

**Lemma 3.1.** Let Hypothesis 1 be satisfied. Then the following assertions hold.

(i) \( X^+_s(0) + X^-_u(0) = X^+_{0,s} \);

(ii) \( X^+_s(0) \cap X^-_u(0) = X_0 \).

**Proof.** (i) Let \( \xi = (\xi_n)_{n \in \mathbb{Z}} \in \ker D^s \). Then \( \xi \) is bounded, and \( U(k,0)^s\xi_k = \xi_0 \) by (2.5). For \( x \in X^+_s(0) \), equation (3.1) yields \( U(k,0)x \to 0 \) as \( k \to \infty \). We compute
\[ \langle x, \xi_0 \rangle = \langle x, U(k,0)^s\xi_k \rangle = \langle U(k,0)x, \xi_k \rangle \]
for all \( k \geq 0 \). Letting \( k \to \infty \), we deduce \( \langle x, \xi_0 \rangle = 0 \) and thus \( x \in X^+_{0,s} \). For \( x \in X^-_u(0) \), there is \( (x_k)_{k \in \mathbb{Z}} \in \mathcal{E}(\mathbb{Z}_-) \) such that \( x_n = U(n,m)x_m \) for all \( m \leq n \leq 0 \) and \( x_0 = x \) due to (3.2). In this case we have \( x_k \to 0 \) as \( k \to -\infty \) and
\[ \langle x, \xi_0 \rangle = \langle x, U(0,k)^s\xi_k \rangle = \langle x_k, U(0,k)^s\xi_0 \rangle = \langle x_k, \xi_k \rangle \]
for all \( k \leq 0 \). Letting \( k \to -\infty \), we now infer that \( x \in X^+_{0,s} \). Hence, \( X^+_s + X^-_u \subseteq X^+_{0,s} \).

Assume that \( x \in X^+_{0,s} \). Then the sequence \( y = -\chi_{\{1\}} \otimes U(1,0)x \) belongs to \( \mathcal{F} \) due to (2.7) and Lemma 2.1(vi). Lemma 2.2(i) gives a sequence \( x = (x_n)_{n \in \mathbb{Z}} \in \mathcal{F} \) with \( Dx = y \). This equation implies that \( x_1 - U(1,0)x_0 = y_1 = -U(1,0)x \) and \( x_n - U(n,1)x_1 = y_n = 0 \) for \( n \geq 2 \). We conclude that \( U(n,0)(x - x_0) = -x_n \) for all \( n \geq 1 \), and thus \( x - x_0 \in X^+_s(0) \) by (3.1). Using \( Dx = y \) again, we obtain \( x_n - U(n,m)x_m = y_n = 0 \) for all \( m \leq n \leq 0 \), so that \( x_0 \in X^-_u(0) \) by (3.2). Therefore, \( x = x - x_0 + x_0 \in X^+_s(0) + X^-_u(0) \), proving (i).

(ii) Let \( x \in X^+_s(0) \cap X^-_u(0) \). Then \( x_n = U(n,0)x \) defines a sequence \( (x_n)_{n \in \mathbb{Z}_+} \in \mathcal{E}(\mathbb{Z}_+) \) by (3.1), and there is a sequence \( (x_n)_{n \in \mathbb{Z}_-} \in \mathcal{E}(\mathbb{Z}_-) \) so that \( x_0 = x \) and \( x_n = U(n,m)x_m \) for all \( m \leq n \leq 0 \) due to (3.2). It is easy to check that \( x_n = U(n,m)x_m \) for all \( n \geq m \) in \( \mathbb{Z} \), and thus \( x \in X_0 \) by (2.2) and (2.4). Hence, \( X^+_s(0) \cap X^-_u(0) \subseteq X_0 \). The converse inclusion follows directly from the definitions of \( X_0, X^+_s(0) \), and \( X^-_u(0) \) in (2.2), (3.1), and (3.2).

**Remark 3.2.** Using the same arguments as in the proof part (i) of Lemma 3.1, one can establish that \( X^+_s(k) \subseteq X^+_{k,s} \) for all \( k \geq 0 \) and \( X^-_u(k) \subseteq X^-_{k,s} \) for all \( k \leq 0 \).

In the derivation of the dichotomy estimates we make use of the following sequences, where \( n \in \mathbb{Z}_+ \) and \( p \in [1, \infty) \):
\[ \alpha_n = \begin{cases} (n + 1)^{1 - \frac{1}{p}} & \text{if } \mathcal{E}(\mathbb{Z}) = \ell^p(\mathbb{Z}, X), \\ (n + 1)^{\frac{1}{p}} & \text{if } \mathcal{E}(\mathbb{Z}) = c_0(\mathbb{Z}, X), \end{cases} \]
\[ \beta_n = \begin{cases} (n + 1)^{\frac{1}{p}} & \text{if } \mathcal{E}(\mathbb{Z}) = \ell^p(\mathbb{Z}, X), \\ 1 & \text{if } \mathcal{E}(\mathbb{Z}) = c_0(\mathbb{Z}, X). \end{cases} \]

**Remark 3.3.** We note some obvious properties of the above sequences.

(i) \( \alpha_n \beta_n = n + 1 \) for all \( n \geq 0 \);

(ii) \( \sum_{k=m}^{m+n} \|x_k\| \leq \alpha_n \|x\|_{\mathcal{E}(\mathbb{Z})} \) for all \( m \in \mathbb{Z}, n \geq 0, x = (x_k)_{k \in \mathbb{Z}} \in \mathcal{E}(\mathbb{Z}). \)
Let Hypothesis 1 be satisfied. Then the following assertions hold.

(i) \[ \| U^+(s, n, m) \| \leq N e^{-\nu(n-m)} \text{ for all } n \geq m \geq 0; \]

(ii) \( X^+_s(m) \) is a closed subspace of \( X \) for all \( m \geq 0 \).

Proof. Let \( m \geq 0 \), \( x \in X^+_s(m) \), and \( (\varphi_k)_{k \in \mathbb{Z}} \) be a finitely supported numerical sequence. We define the sequences \( x = (x_k)_{k \in \mathbb{Z}} \) and \( y = (y_k)_{k \in \mathbb{Z}} \) by

\[
x_k = \begin{cases} 0, & k \leq m, \\ \left( \sum_{j=m+1}^{k} \varphi_j \right) U(k, m)x, & k > m, \\ \end{cases} \quad y_k = \begin{cases} 0, & k \leq m, \\ \varphi_k U(k, m)x, & k > m. \end{cases}
\] (3.5)

Remark 3.2 and (3.3) imply that \( x \in \mathcal{F}_0 \), see (2.8). It is straightforward to check that \( y = D_0 x \). We first take \( (\varphi_k)_{k \in \mathbb{Z}} = \chi(\{l, \ldots, n\}) \). For \( x \) and \( y \) defined in (3.5), estimate (3.6), Remark 3.3, and Lemma 2.2(ii) imply that

\[
\| U(n, m)x \| = \left\| \sum_{j=0}^{n} \chi_{\{l, \ldots, n\}}(j) U(n, m)x \right\| \leq \| x \| \| \varphi \| \leq c \| D_0 x \| \leq c \| y \| \leq c \| U(n+1, m)x \| \leq c M e^\nu \| x \|
\]

for all \( n \geq m + 1 \). It follows that

\[
\| U^+_s(k, j) \| \leq c \quad \text{ for all } k \geq j \geq 0.
\] (3.6)

Second, we take \( n > l > m \) and set \( (\varphi_k)_{k \in \mathbb{Z}} = \chi(\{l, \ldots, n\}) \). For \( x \) and \( y \) defined in (3.5), estimate (3.6), Remark 3.3, and Lemma 2.2(ii) imply that

\[
\frac{1}{2} (n-l+2)(n-l+1) \| U^+_s(n, m)x \| = \sum_{k=l}^{n} (k-l+1) \| U^+_s(n, k)U^+_s(k, m)x \|
\]

\[
\leq c \sum_{k=l}^{n} \sum_{j=m+1}^{k} \varphi_j \| U(k, m)x \| = c \sum_{k=l}^{n} \| x_k \| \leq c \alpha_{n-l} \| x \| \| \varphi \| \leq c \alpha_{n-l} \| y \| \leq c \alpha_{n-l} \| \chi(\{l, \ldots, n\}) \| \leq c \alpha_{n-l} \| U^+_s(l, m)x \| \leq c \alpha_{n-l} \| U^+_s(l, m)x \| = c (n-l+1) \| U^+_s(l, m)x \|
\]

So we have shown that \( \| U(n, m)x \| \leq b_{n-l} \| U(l, m)x \| \) for all \( n \geq l \geq m \geq 0 \) and \( x \in X^+_s(m) \), where \( b_0 = 1 \) and \( b_j = c(j+2)^{-1} \) for \( j \geq 1 \). By Lemma 2.4, there are \( N, \nu > 0 \) such that \( \| U(n, m)x \| \leq N e^{-\nu(n-m)} \| U(l, m)x \| \) for all \( n \geq l \geq m \) and \( x \in X^+_s(m) \), which proves (i). Assertion (ii) follows easily from (i) and (3.1). \( \square \)

Lemma 3.3. Let Hypothesis 1 be satisfied. Then the following assertions hold.

(i) \( U^+_n(n, m) : X^+_n(m) \rightarrow X^+_n(n) \) is bijective for \( m \leq n \leq 0 \);

(ii) There are constants \( N, \nu > 0 \) such that

\[
\| (U^+_n(n, m))^{-1} \| \leq N e^{-\nu(n-m)} \quad \text{ for all } m \leq n \leq 0;
\]

(iii) \( X^+_n(k) \) is a closed subspace of \( X \) for \( k \leq 0 \).
Proof. (i) Fix \( m \leq n \leq 0 \). The surjectivity of \( U_u^-(n, m) \) was already stated in (3.4). Take \( x \in X_u^-(m) \) with \( 0 = U_u^-(n, m)x = U(n, m)x \). By (3.2) there is a sequence \( x = (x_k)_{k \in \mathbb{Z}_-} \in \mathcal{E}(\mathbb{Z}_-) \) such that \( x_k = U(k, j)x_j \) for all \( j \leq k \leq 0 \) and \( x = x_m \). We extend \( x \) to a sequence from \( x \in \mathcal{E}(\mathbb{Z}) \) by setting \( x_k = 0 \) for \( k > 0 \). Since \( x_0 = U(0, n)U(n, m)x = 0 \), the sequence \( x \) belongs to \( \ker D \). Hence, \( x \in X_m \) by (2.2). Lemma 2.1(iii) now yields \( x = (x_k)_{k \in \mathbb{Z}} \) such that \( y \in F \), (iii) It suffices to consider \( k = 0 \) due to (i) and (ii). Take \( x \in X \) and \( x^{(n)} \in X_u^+(0), n \in \mathbb{Z}_+ \), with \( x^{(n)} \rightarrow x \) as \( n \rightarrow \infty \). Let \( y^{(n)} = (y^{(n)}_k)_{k \in \mathbb{Z}_-} \) be a sequence in \( \mathcal{E}(\mathbb{Z}_-) \) such that \( y^{(n)}_k = U(k, j)y^{(n)}_j \) for all \( j \leq k \leq 0 \) and \( y^{(n)}_0 = x^{(n)} \) for all \( n \geq 0 \). Assertion (ii) yields
\[
\|y^{(n)}_k - y^{(m)}_k\| = \|(U_u^-((0, k))^{-1}(x^{(n)} - x^{(m)}))\| \leq N e^{\nu k} \|x^{(n)} - x^{(m)}\|
\]
for all \( n, m \geq 0 \) and all \( k \leq 0 \), and thus
\[
\|y^{(n)} - y^{(m)}\|_{\mathcal{E}(\mathbb{Z})} \leq e\|x^{(n)} - x^{(m)}\| \quad \text{for all } n, m \geq 0.
\]
As a result, there exists \( y = (y_k)_{k \in \mathbb{Z}_-} \in \mathcal{E}(\mathbb{Z}_-) \) with \( y^{(n)} \rightarrow y \) in \( \mathcal{E}(\mathbb{Z}_-) \) as \( n \rightarrow \infty \). It follows that \( y_k = U(k, j)y_j \) for all \( j \leq k \leq 0 \) and \( y_0 = x \); i.e., \( x \in X_u^-(0) \). \( \square \)

As a preparation for the following two sections, we construct several splittings of \( X \). Recall from Lemma 2.1 that \( X_{0, \nu} \) is finite dimensional, and let \( \{\xi_1^{(1)}, \ldots, \xi_{d_0}^{(1)}\} \)
Lemma 4.1. Let Hypothesis 1 be satisfied. Then the following assertions hold.

(i) \( X^+ = Z_1 \oplus X_0 \) and \( X^- = Z_2 \oplus X_0 \);

(ii) \( X^+_0 = Z_1 \oplus Z_2 \);

(iii) \( X = X^+_0 \ominus \mathbb{K} \oplus (Z_2 \oplus Y) = X^-_0 \ominus (Z_1 \oplus Y) \).

Proof. (i) We have seen in Lemma 3.4(ii) and Lemma 3.5(iii) that \( X^+_0 \) and \( X^-_0 \) are closed subspaces of \( X \). Since \( X^+_0 \) is also a closed subspace of \( X \), the spaces \( Z_1 \) and \( Z_2 \) are closed in \( X \). We have \( Z_1 \cap X_0 = \{0\} \) and \( Z_1 \subset X^+_0 \) by (3.10) and (2.6). Lemma 3.1(ii) yields \( X_0 \subset X^+_0 \), so that \( X_0 + Z_1 \subset X^+_0 \). Let \( x \in X^+_0 \). Then \( x \in X^+_0 \ominus X_0 = X^+_0 \ominus Z_0 \) by Lemma 3.1(ii) and (2.6). So we can write \( x = x_0 + x'_0 \) for some \( x_0 \in X_0 \) and \( x'_0 \in X^+_0 \), implying \( x_0 = x - x_0 \in X^+_0 \). Hence, \( x'_0 \in Z_1 \) by (3.10). Thus the first equation in (i) is verified. The second one can be established in the same way.

(ii) The identities (3.10), Lemma 3.1(ii), and (2.6) yield \( Z_1 \subseteq X'_0 \), \( Z_2 \subseteq X'_0 \), and

\[
Z_1 \cap Z_2 = X'_0 \cap \left( X^+_0 \ominus X^-_0 \right) \cap X^-_0 \cap \left( X'_0 \cap X_0 = \{0\} \right).
\]

Let \( x \in X'_0 \). Then we deduce from (2.6) and Lemma 3.1(i) that \( x \in X^+_0 \ominus X^-_0 = X^+_0 \cap X_0 \). So assertion (i) provides us with \( z_1 \in Z_1 \), \( z_2 \in Z_2 \), and \( v_1, v_2 \in X_0 \) such that \( x = z_1 + z_2 + v_1 + v_2 \). Using again \( Z_j \subseteq X'_0 \), we obtain that \( v_1 + v_2 = x - z_1 - z_2 \in X'_0 \). Hence, \( v_1, v_2 \in X'_0 \cap X_0 = \{0\} \). So we have shown that \( X'_0 \subseteq Z_1 + Z_2 \), and the desired decomposition holds.

(iii) The spaces \( Z_1 \oplus Y \) and \( Z_2 \oplus Y \) are closed subspaces of \( X \) since \( Z_1 \) and \( Z_2 \) are closed in \( X \) by (i) and

\[
\dim Y < \infty \text{ by (3.9). We then derive the splitting } X = X_0 \oplus Z_1 \oplus Z_2 \oplus Y \text{ from (3.9), (2.6), and (ii). Hence, (iii) follows from (i).}
\]

4. Exponential dichotomy on \( Z_+ \cap [b, \infty) \)

The main difficulty in establishing the dichotomy on \( Z_+ \cap [b, \infty) \) is the construction of the correct complement of the stable subspace \( X^+_0 (k) \). To that purpose, we first deal with the ‘good part’ of \( X^+_0 (k) \) by propagating the space \( Z_2 \) from (3.10); i.e., we set

\[
Z_2 (k) = U(k, 0)Z_2 \quad \text{for } k \in Z_+.
\]

Observe that, due to (3.10), a vector \( x \in Z_2 \) can be propagated backwards to an element \( (x_n)_{n \in \mathbb{Z}_-} \) of \( E(\mathbb{Z}_-) \) with \( x = U(0, n)x_n \), but this sequence can not be extended to a non-zero element of \( \ker D \). These facts are crucial for the next result.

Lemma 4.1. Let Hypothesis 1 be satisfied. Then the following assertions hold.

(i) \( U(n, m)_{|Z_2 (m)} \) is bijective from \( Z_2 (m) \) to \( Z_2 (n) \) for all \( n \geq m \geq 0 \);

(ii) There are constants \( N, \nu > 0 \) such that

\[
\|(U(n, m)_{|Z_2 (m)})^{-1}\| \leq Ne^{-\nu(n-m)} \quad \text{for all } n \geq m \geq 0;
\]
(iii) $Z_2(k)$ is a closed subspace of $X$ for all $k \geq 0$.

Proof. (i) The definition (4.1) implies that $U(n,m)Z_2(m) = Z_2(n)$ for all $n \geq m \geq 0$. Take $x \in Z_2(m)$ with $U(n,m)x = 0$. By (4.1), there exists a vector $z_2 \in Z_2$ such that $x = U(m,0)z_2$. Since

$$U(j,0)z_2 = U(j,n)U(n,m)U(m,0)z_2 = U(j,n)U(n,m)x = 0$$

for all $j \geq n$, we obtain $z_2 \in X^{+}_n(0)$ (see (3.1)). Lemma 3.6(iii) then shows that $z_2 = 0$, and so $x = 0$. Thus $U(n,m) : Z_2(m) \to Z_2(n)$ is bijective.

(ii) Let $z_2 \in Z_2 \setminus \{0\}$. By (3.10) and (3.2) there is a sequence $w = (w_k)_{k \in \mathbb{Z}_-} \in \mathcal{E}(\mathbb{Z}_-)$ such that $w_k = U(k,j)w_j$ for all $j \leq k \leq 0$ and $w_0 = z_2$. Let $(\varphi_k)_{k \in \mathbb{Z}}$ be a finitely supported numerical sequence. Define $x = (x_k)_{k \in \mathbb{Z}}$ and $y = (y_k)_{k \in \mathbb{Z}}$ by

$$x_k = \begin{cases} \sum_{j=k+1}^{\infty} \varphi_j U(k,0)z_2, & k \geq 1, \\ \sum_{j=1}^{\infty} \varphi_j w_k, & k \leq 0, \end{cases} \quad y_k = \begin{cases} -\varphi_k U(k,0)z_2, & k \geq 1, \\ 0, & k \leq 0. \end{cases}$$

We have $w_k \in X^{+}_n(k) \subseteq X^{+}_n$ for all $k \leq 0$ due to (3.2) and Remark 3.2. Equations (3.10) and (2.6) and Lemma 2.1(vi) further imply that $U(k,j)w_j$ for all $j \leq k \leq 0$. Since also $x \in \mathcal{E}(\mathbb{Z})$ and $w_0 = z_2 \in X^+_0$ by (3.10), the vector $x$ belongs to $\mathcal{F}_0$ (see (2.8)). Moreover, $y = Dx = D_0x$. Let $n > m \geq 0$. Choose first $(\varphi_k)_{k \in \mathbb{Z}} = \chi(n)$. Then Lemma 2.2(ii) yields

$$\|U(m,0)z_2\| = \|x_m\| \leq \|x\|_{\mathcal{E}(\mathbb{Z})} \leq c\|y\|_{\mathcal{E}(\mathbb{Z})} \leq c\|U(n,0)z_2\|. \quad (4.2)$$

Second, take $(\varphi_k)_{k \in \mathbb{Z}} = \chi_m(1,\ldots,n)$. In this case, estimate (4.2), Remark 3.3, and Lemma 2.2(ii) imply that

$$\frac{1}{2} (n-m)(n-m+1)\|U(m,0)z_2\|^2 = \sum_{k=m}^{n-1} (n-k)\|U(m,0)z_2\|^2 \leq \sum_{k=m}^{n-1} \sum_{j=k+1}^{\infty} \varphi_j \|U(m,0)z_2\|^2 \leq c \sum_{k=m}^{n-1} \sum_{j=k+1}^{\infty} \varphi_j \|U(k,0)z_2\| \leq c \sum_{k=m}^{n-1} \|x_k\|$$

$$\leq c \alpha_{n-m-1}\|x\|_{\mathcal{E}(\mathbb{Z})} \leq c \alpha_{n-m-1}\|y\|_{\mathcal{E}(\mathbb{Z})}$$

$$\leq c \alpha_{n-m-1}\|\chi_m(1,\ldots,n) \otimes U(n,0)z_2\|_{\mathcal{E}(\mathbb{Z})} \leq c \alpha_{n-m-1}\|U(n,0)z_2\| = (c(n-m)-1)\|U(n,0)z_2\|.$$

Therefore $\|U(m,0)z_2\| \leq \frac{c}{n-m+1}\|U(n,0)z_2\|$, and in particular $U(n,0)z_2 \neq 0$, for all $n \geq m \geq 0$. Applying Lemma 2.4 to the sequences $a_n = \|U(n,0)z_2\|^{-1}$ and $b_n = c(n+1)^{-1}$, we obtain constants $N, \nu > 0$ (independent of $z_2$) such that $\|U(m,0)z_2\| \leq Ne^{\nu(n-m)}\|U(n,0)z_2\|$ for all $n \geq m \geq 0$. Using (i), we can now conclude that (ii) holds.

(iii) Since $U(k,0)z_2(0) : Z_2(0) \to Z_2(k)$ is an isomorphism by (i) and (ii), the last assertion follows from (4.1) and the closedness of $Z_2$ proved in Lemma 3.6(i). \qed

We next introduce the remaining complement of the unstable subspace. Let $\{\xi^{(1)}_b, \ldots, \xi^{(d_b)}_b\}$ be a basis of $X^{+}_{b,*}$ (cf. Lemma 2.1). By Lemma 2.3(i), there are vectors $x^{(1)}_b, \ldots, x^{(d_b)}_b$ in $X$ such that $\langle x^{(i)}_b, \xi^{(j)}_b \rangle = \delta_{ij}$ for all $i, j \in \{1, \ldots, d_b\}$. Lemma 2.3(ii) shows that

$$X = X^{+}_{b,*} \oplus Y^{+}(b), \quad \text{where } Y^{+}(b) := \text{Span}\{x^{(1)}_b, \ldots, x^{(d_b)}_b\}. \quad (4.3)$$
We note that $Z_2$ is contained in $X_{n,*}^+$ due to (3.10) and (2.6). Lemma 2.1(vi) and equation (4.1) then imply that
\[ Z_2(n) = U(n,0)Z_2 \subset X_{n,*}^+ \quad \text{for all } n \in \mathbb{Z}_+. \tag{4.4} \]
Hence, $Z_2(b) \cap Y^+(b) = \{0\}$. Moreover, $Z_2(b)$ is closed by Lemma 4.1(iii). So we can define a closed subspace of $X$ by
\[ X_{n,*}^+(b) = Z_2(b) \oplus Y^+(b). \tag{4.5} \]
We see below that $X_{n,*}^+$ is indeed the unstable subspace. We propagate these spaces by the evolution family; i.e., we set
\[ X_{k}^+(b) = U(k,b)X_{n,*}^+(b) \quad \text{and} \quad Y^+(k) = U(k,b)Y^+(b) \quad \text{for all } k \geq b. \tag{4.6} \]
Finally, we let $U_n^+(n,m) = U(n,m)_{X_{n}^+(m)}$ for $n \geq m \geq b$. Here we take $k \geq b$ in order to make sure that $\dim X_{k,*}$ and thus $\dim X_k^+(b)$, is constant.

**Lemma 4.2.** Let Hypothesis 1 be satisfied. Then the following assertions hold.

(i) $X_n^+(k)$ is closed in $X$ and $X_n^+(k) = Z_2(k) \oplus Y^+(k)$ for all $k \geq b$;

(ii) $U_n^+(n,m)$ is invertible from $X_n^+(m)$ to $X_n^+(n)$ and $U(n,m)_{Y^+(m)}$ is invertible from $Y^+(m)$ to $Y^+(n)$ for all $n \geq m \geq b$;

(iii) $X = Y^+ \oplus X_{k,*}$ for all $k \geq b$.

**Proof.** (i) Let $w \in Z_2(k) \cap Y^+(k)$ for some $k \geq b$. Then $w = U(k,b)x$ for a vector $x \in Z_2(b) \cap Y^+(b)$ by Lemma 4.1(i) and (4.6). Thus equation (4.5) yields $x = 0$, and so $w = 0$. Moreover, $Z_2(k) \oplus Y^+(k)$ is closed since $Z_2(k)$ is closed by Lemma 4.1(iii) and $Y^+(k)$ is finite dimensional by (4.3). Assertion (i) is now a consequence of (4.6), (4.5), and Lemma 4.1(i).

(ii) Let $n \geq m \geq b$. The surjectivity of $U(n,m) : X_n^+(m) \to X_n^+(n)$ and of $U(n,m) : Y^+(m) \to Y^+(n)$ follows from (4.6). Take $x \in X_n^+(m)$ with $U_n^+(n,m)x = 0$. By our definitions (4.6), (4.5), and (4.1), there are $z_2 \in Z_2$ and $y_b \in Y^+(b)$ such that $x = U(m,b)(U(b,0)z_2 + y_b)$. Therefore, $0 = U(n,m)x = U(n,0)z_2 + U(n,b)y_b$. On the other hand, $U(n,0)z_2 \in X_{n,*}^+$ by (4.4). For $\xi = (\xi_k)_{k \in \mathbb{Z}} \in \ker D^*$ equation (2.5) thus yields
\[ \langle y_b, \xi_b \rangle = \langle y_b, U(n,b)^*\xi_n \rangle = \langle U(n,b)y_b, \xi_n \rangle = -\langle U(n,0)z_2, \xi_n \rangle = 0. \]
We obtain $y_b \in X_{n,*}^+ \cap Y^+(b) = \{0\}$ taking into account (4.3). As a result, $U(j,0)z_2 = U(j,n)U(n,0)z_2 = 0$ for all $j \geq n$, which means that $z_2 \in X_n^+(0) \cap Z_2$. Lemma 3.6(iii) now yields $z_2 = 0$. This fact leads to $x = 0$, and so $U_n^+(n,m) : X_n^+(m) \to X_n^+(n)$ is also injective. The assertions then follow from (i) and (4.6).

(iii) As we have seen before (4.3), there exist bases $\{\xi_b^{(1)}, \ldots, \xi_b^{(d_b)}\}$ of $X_{k,*}$ and $\{x_b^{(1)}, \ldots, x_b^{(d_b)}\}$ of $Y^+(b)$ such that $\langle x_b^{(i)}, \xi_b^{(j)} \rangle = \delta_{ij}$ for all $i, j \in \{1, \ldots, d_b\}$. Lemma 2.1(iv) and part (ii) show that $\{(U(k,b)^*)^{-1}\xi_b^{(1)}, \ldots, (U(k,b)^*)^{-1}\xi_b^{(d_b)}\}$ is a basis of $X_{k,*}$ and $\{U(k,b)x_b^{(1)}, \ldots, U(k,b)x_b^{(d_b)}\}$ is a basis of $Y^+(k)$. Moreover $\langle U(k,b)x_b^{(i)}, (U(k,b)^*)^{-1}\xi_b^{(j)} \rangle = \delta_{ij}$ for all $i, j \in \{1, \ldots, d_b\}$. Lemma 2.3(ii) thus yields the assertion. \hfill $\Box$

Let $n \in \mathbb{Z}_+$ and $p \in [1, \infty)$. The following sequences are used below when we estimate the inverses of $U^+_n(n,m)$.
\[
\alpha_n = \begin{cases} 
(n + 1)^{\frac{1}{p}} & \text{if } E(\mathbb{Z}) = L^p(\mathbb{Z}, X), \\
(n + 1)^{1 - \frac{1}{p}} & \text{if } E(\mathbb{Z}) = c_0(\mathbb{Z}, X), \\
1 & \text{if } E(\mathbb{Z}) = \ell^p(\mathbb{Z}, X); 
\end{cases} \\
\beta_n = \begin{cases} 
(n + 1)^{\frac{1}{p}} & \text{if } E(\mathbb{Z}) = \ell^p(\mathbb{Z}, X), \\
1 & \text{if } E(\mathbb{Z}) = c_0(\mathbb{Z}, X). 
\end{cases}
\]
Remark 4.3. We note some immediate properties of the above defined sequences.

(i) \( \alpha_n^* \beta_n^* = n + 1 \) for \( n \geq 0 \);
(ii) \( \sum_{k=m}^{n+m} \| \xi_k \| \leq \alpha_n^* \| \xi \|_{E(Z)^*} \) for \( m \in \mathbb{Z}, n \geq 0, \xi = (\xi_k)_{k \in \mathbb{Z}} \in E(\mathbb{Z})^* \);
(iii) \( \| \chi_{\{m, \ldots, m+n\}} \otimes \xi \|_{E(Z)^*} = \beta_n^* \| \xi \| \) for \( \xi \in X^*, m \in \mathbb{Z}, n \geq 0 \).

Lemma 4.4. Let Hypothesis 1 be satisfied. Then the following assertions hold.

(i) There are constants \( N, \nu > 0 \) such that

\[
\| (U(n, m)_{X_n^*})^{-1} \| \leq Ne^{-\nu(n-m)} \quad \text{for} \quad n \geq m \geq b;
\]

(ii) There are constants \( N, \nu > 0 \) such that

\[
\| (U^+(n, m))^{-1} \| \leq Ne^{-\nu(n-m)} \quad \text{for} \quad n \geq m \geq b.
\]

Proof. (i) Let \( \xi = (\xi_k)_{k \in \mathbb{Z}} \in \ker D^* \) and \( (\varphi_k)_{k \in \mathbb{Z}} \) be a finitely supported numerical sequence. We define the sequences \( \eta = (\eta_k)_{k \in \mathbb{Z}} \) and \( \zeta = (\zeta_k)_{k \in \mathbb{Z}} \) by

\[
\eta_k = \begin{cases} 0, & k \leq b, \\ \left( \sum_{j=b+1}^{k} \varphi_j \right) \xi_k, & k \geq b + 1, \end{cases} \quad \zeta_k = \begin{cases} 0, & k \leq b - 1, \\ -\varphi_{k+1} \xi_k, & k \geq b.
\end{cases}
\]

We have \( \eta \in F_{b, +} \) since \( \xi \in \ker D^* \) and \( \eta_b = 0 \) (see (2.3) and (2.9)). Moreover, \( \zeta = D^* \eta = D_{b, +} \eta \). Let \( n \geq m + 1 \geq b \). We first choose \( (\varphi_k)_{k \in \mathbb{Z}} = \chi_{\{m+1, \ldots, n\}} \). Making use of estimate (4.7), Remark 4.3, and Lemma 2.2(iii) yields

\[
\| \xi_n \| = \| \eta_n \| \leq \| \eta \|_{E(Z)^*} \leq c \| \zeta \|_{E(Z)^*} = c \| \xi_m \|.
\]

(4.7)

Second, choose \( (\varphi_k)_{k \in \mathbb{Z}} = \chi_{\{m+1, \ldots, n\}} \). We calculate

\[
\frac{1}{2} (n - m)(n - m + 1) \| \xi_n \| = \sum_{k=m+1}^{n} (k - m) \| \xi_n \| \leq c \sum_{k=m+1}^{n} \sum_{j=b+1}^{k} \varphi_j \| \xi_j \|
\]

\[
= c \sum_{k=m+1}^{n} \| \eta_k \| \leq c \alpha_{n-m-1} \| \eta \|_{E(Z)^*} \leq c \alpha_{n-m-1} \| \zeta \|_{E(Z)^*}
\]

\[
= c \alpha_{n-m-1} \beta_{n-m-1} \| \xi_m \| = c(n - m) \| \xi_m \|.
\]

As a result, \( \| \xi_n \| \leq \frac{c(n - m)}{n - m + 1} \| \xi_m \| \) for all \( n \geq m \geq b \). Lemma 2.4 provides constants \( N, \nu > 0 \) (independent of \( \xi \)) such that \( \| \xi_n \| \leq Ne^{-\nu(n-m)} \| \xi_m \| \) for all \( n \geq m \geq b \) and \( \xi = (\xi_k)_{k \in \mathbb{Z}} \in \ker D^* \), proving (i).

(ii) The decomposition \( X = Y^+(k) \oplus X^+_k \) from Lemma 4.2(iii) implies that \( Y^+(k)^* = X^+_k \) for all \( k \geq b \) since \( X^+_k \) is finite dimensional. Thus we have

\[
((U(n, m)_{Y^+(m)})^{-1})^* = ((U(n, m)_{Y^+(m)})^*)^{-1} = (U(n, m)_{X^+_n})^{-1}
\]

for all \( n \geq m \geq b \) by Lemmas 4.2(ii) and 2.1(iv). Assertion (i) now yields

\[
\| (U(n, m)_{Y^+(m)})^{-1} \| \leq Ne^{-\nu(n-m)} \quad \text{for} \quad n \geq m \geq b.
\]

(4.8)

Lemmas 4.1 and 4.2 show that \( U^+(n, m)^{-1} \) has the matrix representation

\[
\begin{bmatrix} (U(n, m)_{Z_2^+(m)})^{-1} & 0 \\ 0 & (U(n, m)_{Y^+(m)})^{-1} \end{bmatrix} : Z_2^+(m) \oplus Y^+(m) \longrightarrow Z_2(n) \oplus Y^+(n)
\]

for all \( n \geq m \geq b \). So the assertion follows from Lemma 4.1(ii) and (4.8). \( \square \)
Theorem 4.5. Let Hypothesis 1 hold. Then $U$ has an exponential dichotomy on $\mathbb{Z}_+ \cap [b, \infty)$ with subspaces $X_+^+(k)$ and $X_u^+(k)$ given by (3.1) and (4.6), respectively.

Proof. The spaces $X_+^+(m)$ and $X_u^+(m)$, $m \geq b$, are closed and invariant under $U(n, m)$ due to Lemmas 3.4 and 4.2 and formula (3.3). We have shown the invertibility of $U_+^+(n, m) : X_+^+(m) \to X_+^+(n)$ in Lemma 4.2(ii), and the exponential estimates of $U_+^+(n, m)$ and $U_u^+(n, m)^{-1}$ in Lemmas 3.4 and 4.4. It remains to verify that $X_+^+(m) \oplus X_u^+(m) = X$ for $m \geq b$. In view of Lemma 4.2 this fact follows from the decomposition

$$X_{m, s}^+ = X_+^+(m) \oplus Z_2(m) \quad \text{for all } m \geq 0. \quad (4.9)$$

We prove (4.9). Let $x \in X_{s}^+(m) \cap Z_2(m)$ for some $m \geq 0$. Then Lemma 4.1(ii) and Lemma 3.4(i) yield

$$\|x\| \leq N e^{-\nu(n-m)} \|U(n, m)x\| \leq N^2 e^{-\nu(n-m)}\|x\| \quad \text{for all } n \geq m,$$

which implies that $x = 0$. Take $x \in X_{m, s}^+$ for some $m \geq 0$. We define the sequence $y = -\chi_{(m+1)} \oplus U(m+1, m)x$ which belongs to $\mathcal{F}$ by Lemma 2.1(ii) and (2.7). Lemma 2.2(i) gives a sequence $x = (x_k)_{k \in Z} \in \mathcal{F}$ such that $Dx = y$. It follows that

$$x_k - U(k, k-1)x_{k-1} = y_k = 0 \quad \text{for all } k \in Z \setminus \{m + 1\},$$

$$x_{m+1} - U(m+1, m)x_m = -U(m+1, m)x. \quad (4.10)$$

Therefore $x_k = U(k, j)x_j$ for all $j \leq k \leq 0$, and so $x_0 \in X_u^-(0) = Z_2 \oplus X_0$ by (3.2) and Lemma 3.6(i). Thus we can write $x_0 = z_2 + v_0$ with $z_2 \in Z_2$ and $v = (v_k)_{k \in Z} \in \ker D$ (see (2.2)). The equations (4.10) further yield $x_j = U(j, m)(x_m - x)$ for all $j \geq m + 1$ and $x_m = U(m, 0)x_0 = U(m, 0)z_2 + v$, using also (2.4). We then deduce

$$U(j, m)(x - U(m, 0)z_2) = -x_j + U(j, m)(x_m - U(m, 0)z_2) = -x_j + v_j$$

for all $j \geq m + 1$. The vector $x - U(m, 0)z_2$ thus belongs to $X_u^+(m)$ since $x, v \in \mathcal{E}(Z)$ (see (3.1)). We thus obtain $x = (x - U(m, 0)z_2) + U(m, 0)z_2 \in X_u^+(m) + Z_2(m)$ due to Lemma 4.1(i); i.e., $X_{m, s}^+ \subseteq X_u^+(m) + Z_2(m)$. The converse inclusion follows from Remark 3.2 and (4.4). \qed

5. Exponential dichotomy on $\mathbb{Z}_-$

The situation on $\mathbb{Z}_-$ is simpler than in the previous section since we have dealt with the unstable subspaces already in Lemma 3.5. We first define our candidates for the stable subspaces on $\mathbb{Z}_-$ by setting

$$X_s^-(0) = Z_1 \oplus Y \quad \text{and} \quad X_s^-(k) = \{x \in X : U(0, k)x \in X_s^-(0)\} \quad (5.1)$$

for all $k \in \mathbb{Z}_-$. Recall from (3.9) that $Y$ is finite dimensional and from Lemma 3.6 that $Z_1$ is closed and $Z_1 \cap Y = \{0\}$. We further denote $U_s^-(n, m) = U(n, m)|_{X_s^-(m)}$ for $m \leq n \leq 0$, and we introduce the auxiliary spaces

$$Z_1(k) = \{x \in X : U(0, k)x \in Z_1\} \subseteq X_s^-(k) \quad \text{for all } k \in \mathbb{Z}_-. \quad (5.2)$$

Remark 5.1. Since the subspaces $X_s^-(0)$ and $Z_1$ are closed, $X_s^-(m)$ and $Z_1(m)$ are closed subspaces of $X$ for all $m \in \mathbb{Z}_-$. Moreover, $U(n, m)X_s^-(m) \subseteq X_s^-(n)$ and $U(n, m)Z_1(m) \subseteq Z_1(n)$ for all $m \leq n \leq 0$. \hfill \Box

Lemma 5.2. Let Hypothesis 1 hold. Then the following assertions hold for $k \leq 0$.

(i) $Z_1(k) = X_s^-(k) \cap X_{u}^+(k)$;

(ii) $X = X_s^-(k) \oplus X_u^-(k)$. 

Proof. (i) Since $Z_1 \subseteq X^+_{0,s}$ by (3.10) and (2.6), Lemma 2.1(vi) and (5.2) yield $Z_1(k) \subseteq X^-_{s}(k) \cap X^+_{0,s}$ for $k \in \mathbb{Z}$. Let $x \in X^+_{0,s} \cap X^-_{s}(k)$. Due to (5.1), there are $z_1 \in Z_1$ and $y \in Y$ such that $U(0,k)x = y + z_1$. We take $\xi = (\xi_n)_{n \in \mathbb{Z}} \in \ker D^*$ and calculate

$$
(y, \xi_0) = \langle U(0,k)x, \xi_0 \rangle - \langle z_1, \xi_0 \rangle = \langle x, U(0,k)^*\xi_0 \rangle = \langle x, \xi_k \rangle = 0
$$

using (2.5) and $Z_1 \subseteq X^+_{0,s}$. So we obtain $y \in Y \cap X^+_{0,s} = \{0\}$ employing also (3.9). Hence, $U(0,k)x = z_1 \in Z_1$; i.e., $x \in Z_1(k)$.

(ii) Lemma 3.6(iii) and (5.1) show that $X = X^-_s(0) \oplus X^-_u(0)$. Hence, given $x \in X$, there exist $x_1^- \in X^-_s(0)$ and $x_2^- \in X^-_u(0)$ with $U(0,k)x = x_1^- + x_2^-$. By (3.2) there is a sequence $x = (x_n)_{n \in \mathbb{Z}} \in \mathcal{E}(Z_-)$ such that $x_n = U(n,m)x_m$ for all $m \leq n \leq 0$ and $x_0 = x_2^-$. Observe that $x_k \in X^-_u(k)$ by (3.2). We further compute

$$
U(0,k)(x - x_k) = U(0,k)x - x_2^- = x_1^- \in X^-_s(0),
$$

so that $x - x_k \in X^-_s(k)$ by (5.1). As a result, $X = X^-_s(k) \oplus X^-_u(k)$. Take $x \in X^-_s(k) \cap X^-_u(k)$. Then equation (3.4) yields $U(0,k)x \in X^-_u(0)$. As above we see that $U(k,0)x \in X^-_u(0)$. Hence, $U(0,k)x = 0$ and Lemma 3.5(i) implies $x = 0$. □

Lemma 5.3. Let Hypothesis 1 hold. Then there are constants $N, \nu > 0$ such that

$$
\|U(n,m)\|_{Z_1(m)} \leq Ne^{-\nu(n-m)} \quad \text{for all } m \leq n \leq 0.
$$

Proof. Let $m \leq -1$, $x \in Z_1(m)$, and $(\varphi_k)_{k \in \mathbb{Z}}$ be a finitely supported numerical sequence. We define the sequences $x = (x_k)_{k \in \mathbb{Z}}$ and $y = (y_k)_{k \in \mathbb{Z}}$ by

$$
x_k = \begin{cases} 0, & k \leq m - 1, \\
\sum_{j=m}^{k} \varphi_j U(k,m)x, & m \leq k \leq -1, \\
\sum_{j=m}^{k-1} \varphi_j U(k,m)x, & k \geq 0,
\end{cases}
$$

and

$$
y_k = \begin{cases} 0, & k \leq m - 1, \\
\varphi_k U(k,m)x, & m \leq k \leq -1, \\
0, & k \geq 0.
\end{cases}
$$

We have $x \in \mathcal{E}(Z)$ and $x_0 \in X_0^0$ because of $U(0,m)Z_1(m) \subseteq Z_1 \subseteq X^+_s(0) \cap X^+_0$ (see (5.2), (3.10), and (3.11)). Lemmas 5.2(i) and 2.1(vi) further yield $U(k,m)x \in X^+_0$ for $k \geq m$. Therefore $x \in F_0$ (see (2.8)). Moreover, $y = Dx = D_0x$. Let $m \leq n \leq -1$. Choose first $(\varphi_k)_{k \in \mathbb{Z}} = \chi_{\{m\}}$. Using Lemma 2.2(ii), we estimate

$$
\|U(n,m)x\| = \sum_{j=m}^{n} \varphi_j \|U(n,m)x\| \leq \|x\|_{\mathcal{E}(Z)} \leq c\|y\|_{\mathcal{E}(Z)} = c\|x\|. \quad (5.3)
$$

As a consequence of estimate (5.3), Remark 3.3, and Lemma 2.2(ii), we obtain that

$$
\frac{1}{2}(n - m + 1)(n - m + 2)\|U(n,m)x\| = \sum_{k=m}^{n} (k - m + 1)\|U(n,m)x\|
$$

$$
= \sum_{k=m}^{n} \sum_{j=m}^{k} \varphi_j \|U(n,k)U(k,m)x\| \leq \sum_{k=m}^{n} \sum_{j=m}^{k} \varphi_j c\|U(k,m)x\| = c \sum_{k=m}^{n} \|x_k\|
$$

$$
\leq c|\alpha_{n-m}\|x\|_{\mathcal{E}(Z)} \leq c|\alpha_{n-m}\|y\|_{\mathcal{E}(Z)} = c|\alpha_{n-m}\|\beta_{n-m}\|x\| = c(n - m + 1)\|x\|,
$$

It follows that $\|U(n,m)\|_{Z_1(m)} \leq \frac{c}{n - m + \frac{1}{2}}$ for all $m \leq n \leq 0$. This implies the assertion by a standard argument, cf. [8, Theorem III.6.1]. □
\textbf{Lemma 5.4.} Let Hypothesis 1 hold. Then there are constants \(N, \nu > 0\) such that 
\[
\|U(n, m)^\ast_{|X_{n,*}}\| \leq Ne^{-\nu(n-m)} \quad \text{for all } m \leq n \leq 0.
\]

\textit{Proof.} Let \(\xi = (\xi_n)_{n \in \mathbb{Z}} \in \ker D^\ast\) and \((\varphi_k)_{k \in \mathbb{Z}}\) be a finitely supported sequence. Define the sequences \(\eta = (\eta_k)_{k \in \mathbb{Z}}\) and \(\zeta = (\zeta_k)_{k \in \mathbb{Z}}\) by setting 
\[
\eta_k = \begin{cases} 
0, & k \geq 0, \\
-1 & \sum_j \varphi_j \xi_k, & k \leq -1,
\end{cases} \quad \zeta_k = \begin{cases} 
0, & k \geq 0, \\
\varphi_k \xi_k, & k \leq -1.
\end{cases}
\]

Since \(\xi \in \ker D^\ast\), we obtain that \(\eta \in F_{b,}\) (see (2.9) and (2.3)). Moreover, \(\zeta = D\eta = D_{b,}\eta\) due to (2.5). Let \(m \leq n \leq -1\). First choose \((\varphi_k)_{k \in \mathbb{Z}} = \chi_{(n)}\). Then Lemma 2.2(iii) yields 
\[
\|\xi_m\| = \|\eta_m\| \leq \|\eta\|\|\xi(\mathbb{Z})\| \leq c\|\xi(\mathbb{Z})\| = c\|\xi_n\|. \quad (5.4)
\]

Second, choose \((\varphi_k)_{k \in \mathbb{Z}} = \chi_{(m, \ldots, n)}\). Employing inequality (5.4), Remark 4.3, and Lemma 2.2(iii), we can estimate 
\[
\frac{1}{2}(n-m+1)(n-m+2)\|\xi_m\| = \sum_{k=m}^{n}(n-k+1)\|\xi_m\| = \sum_{k=m}^{n-1}(n-k)\|\xi_m\| 
\leq c \sum_{k=m}^{n-1}(n-k)\|\varphi_k\|\|\xi_k\| = c \sum_{k=m}^{n-1}\|\eta_k\| \leq c\alpha_{n-m}^{\ast}\|\eta\|\|\xi(\mathbb{Z})\| \leq c\alpha_{n-m}^{\ast}\|\xi(\mathbb{Z})\|.
\]

Taking into account that \(\|\xi_{-1}\| \leq Me^{\varpi}\|\xi_0\|\), we infer \(\|\xi_m\| \leq \frac{c}{m^\ast+2}\|\xi_m\|\) for all \(m \leq n \leq 0\). An application of Lemma 2.4 to the sequences \(a_j = \|\xi_{-j}\|\) and \(b_j = c(j+2)^{-1}\) gives \(N, \nu > 0\) such that \(\|\xi_m\| \leq Ne^{-\nu(n-m)}\|\xi_0\|\) for all \(m \leq n \leq 0\), proving the lemma. \(\square\)

\textbf{Theorem 5.5.} Let Hypothesis 1 be satisfied. Then \(U\) has an exponential dichotomy on \(\mathbb{Z}_-\) with subspaces \(X_+^\ast(k)\) and \(X_-^\ast(k)\) given by (5.1) and (3.2), respectively.

\textit{Proof.} Property (i) in the definition of exponential dichotomy was established in Lemma 5.2(ii), Remark 5.1, and (3.4). Lemma 3.5 yields property (ii) and the second exponential estimate in (iii). In order to prove the remaining estimate for \(U^\ast(n, m)\), we fix a basis \(\{\xi_{(1)}, \ldots, \xi_{(d_0)}\}\) of the space \(X_{\ast,*}\) (which is finite dimensional by Lemma 2.1). There exist sequences \(\eta_1 = (\eta_k^{(1)})_{k \in \mathbb{Z}}, \ldots, \eta_{d_0} = (\eta_k^{(d)})_{k \in \mathbb{Z}}\) belonging to \(\ker D^\ast\) such that \(\eta_0^{(j)} = \xi_{(j)}^{(0)}\) for all \(j \in \{1, \ldots, d_0\}\), see (2.5). Lemma 2.1(iv) implies that \(\{\eta_k^{(1)}, \ldots, \eta_k^{(d_0)}\}\) is a basis of \(X_{\ast,*}\) for all \(k \leq 0\). Using Remark 3.2, we obtain \(X_{\ast,*}(k) \subseteq X_{\ast,*}^{\perp} = \bigcap_{j=1}^{d_0}\ker \eta_k^{(j)}\) for all \(k \leq 0\). As a consequence of Lemmas 2.3(i) and 5.2(ii) we then find vectors \(y_1^{(1)}, \ldots, y_0^{(d_0)}\) contained in \(X_{\ast,*}^\ast(k)\) such that \(\langle y_k^{(i)}, y_k^{(j)} \rangle = \delta_{ij}\) for all \(i, j \in \{1, \ldots, d_0\}\) and \(k \leq 0\). We now define \(Y_\ast(k) = \text{Span}\{y_1^{(1)}, \ldots, y_0^{(d_0)}\}\). From Lemmas 2.3(ii) and 5.2(i) we deduce 
\[
X_{\ast,*}(k) = (X_{\ast,*}(k) \cap X_{\ast,*}^{\perp}) \oplus Y_\ast(k) = Z_1(k) \oplus Y_\ast(k) \quad \text{for all } k \leq 0. \quad (5.5)
\]

Let \(m \leq n \leq 0\). We further introduce the space 
\[
\tilde{Y}_\ast(n, m) = \text{Span}\{U(n, m)y_1^{(1)}, \ldots, U(n, m)y_0^{(d_0)}\} = U(n, m)Y_\ast(m), \quad (5.6)
\]
where \( U(n,m)_{\eta}^{(j)} \in X_\gamma(n) \) for all \( j \in \{1,\ldots,d_0\} \) due to Remark 5.1. Moreover,

\[
(U(n,m)_{\eta}^{(j)}, \eta^{(j)}) = (y^j_m, U(n,m)^*\eta^{(j)}) = (y^j_m, \eta^{(j)}) = \delta_{ij}
\]

for all \( i,j \in \{1,\ldots,d_0\} \) by (2.5). As in (5.5) we can conclude by Lemma 2.3(iii) that

\[
X_\gamma^{-1}(n) = (X_\gamma^{-1}(n) \cap X_n^{\perp}) \oplus \bar{Y}^-(n,m) = Z_1(n) \oplus \bar{Y}^-(n,m). \tag{5.7}
\]

Our construction implies that \( \dim \bar{Y}^-(n,m)^* = \dim X_{n,*} < \infty \). Therefore (5.7) yields \( X_{n,*} \subseteq \bar{Y}^-(n,m)^* \), and hence \( X_{n,*} = \bar{Y}^-(n,m)^* \). Similarly, the equality \( Y^-(m)^* = X_{m,*} \) follows from (5.5). Using Lemma 5.4, we arrive at

\[
\|U(n,m)_{\gamma}^{-1}(m)\| = \|U(n,m)_{\gamma}^{-1}(m)\|^* = \|U(n,m)^*_{X_{n,*}}\| \leq N e^{-\nu(n-m)} \tag{5.8}
\]

for \( m \leq n \leq 0 \) and some constants \( N, \nu > 0 \). In view of (5.5), (5.7), (5.6), and Remark 5.1, the operator \( U_{\gamma}^{-1}(n,m) \) has the matrix representation

\[
\begin{bmatrix}
U(n,m)_{\gamma^{-1}(m)} & 0 \\
0 & U(n,m)_{\gamma^{-1}(m)}
\end{bmatrix}
: Z_1(k) \oplus Y^-(k) \rightarrow Z_1(n) \oplus \bar{Y}^-(n,m).
\]

Thus the exponential stability of \( U_{\gamma}^{-1}(n,m) \) is a consequence of Lemma 5.3 and inequality (5.8).

\[\square\]

6. Proof of Theorem 1.1

**Sufficiency.** Assume that (i) and (ii) in Theorem 1.1 hold. Then the Fredholmity of \( G \) can be shown exactly as in Theorem 1.1 of [12]. (At this point as well as in the proof of Theorem 1.4 and Lemma 1.5 the condition (BU) was not used in [12].)

**Necessity.** Assume that \( G \) is Fredholm. As observed in Section 2, Theorem 1.4 of [12] then implies Hypothesis 1 for \( U \), where we may assume that \( a = 0 \) without loss of generality. Then Theorems 4.5 and 5.5 show that \( U \) has exponential dichotomies on \([b,\infty) \cap \mathbb{Z}_+\) and \( \mathbb{Z}_- \). Lemma 1.5 of [12] (combined with a translation argument) further implies that \( U \) has exponential dichotomies on \( \mathbb{R}_- \) and \([b,\infty) \).

We further have to prove (ii), i.e., the Fredholm property of the node operator \( N(b,0) = (I - P_b^+)U(b,a) : \ker P_0^- \rightarrow \ker P_b^+ \). Lemma 3.6(i) and (4.5) yield

\[\ker P_0^- = X_{n}^{-1}(0) = Z_2 \oplus X_0 \quad \text{and} \quad \ker P_b^+ = X_{n}^+(b) = Z_2(b) \oplus Y^+(b). \tag{6.1}\]

Recall from Lemma 2.1 and (4.3) that \( X_{n}^{-1}(b) \) and \( Y^+(b) \) are finite dimensional. Thus the Fredholmity of \( N(b,0) \) follows from the equations

\[\ker N(b,0) = X_0 \quad \text{and} \quad \text{im} N(b,0) = Z_2(b). \tag{6.2}\]

For \( x = (x_n)_{n \in \mathbb{Z}} \in \ker D \) we obtain \( N(b,0)x_0 = (I - P_b^+)x_b = 0 \) using (2.4), so that \( X_0 \subseteq \ker N(b,0) \). Conversely, let \( x \in \ker N(b,0) \subseteq \ker P_0^- \). Due to (6.1) there are \( z_2 \in Z_2 \) and \( x_0 \in X_0 \) with \( x = z_2 + x_0 \). We can then infer \( N(b,0)x_0 = N(b,0)x = 0 \) because of \( X_0 \subseteq \ker N(b,0) \). Since further \( U(b,0)z_2 \in Z_2(b) \subseteq X^+_n(b) = \ker P_b^+ \) by (4.1) and (4.5), we arrive at \( 0 = N(b,0)x = U(b,0)z_2 \). Now Lemma 4.1(i) shows that \( z_2 = 0 \), and thus \( x = x_0 \in X_0 \). By the same arguments we deduce \( \text{im} N(b,0) = N(b,0)Z_2 = (I - P_b^+)Z_2(b) = Z_2(b) \).

Finally, we want to show the index and dimension formulas in Theorem 1.1 assuming that \( G \) is Fredholm. Define \( R_0 : \ker D \rightarrow X_0 \) and \( R_{b,*} : \ker D^- \rightarrow X_{b,*} \) by \( R_0(x_n)_{n \in \mathbb{Z}} = x_0 \) and \( R_{b,*}(\xi_n)_{n \in \mathbb{Z}} = \xi_b \), respectively. The maps \( R_0 \) and \( R_{b,*} \) are surjective linear operators, by (2.4) and (2.5). Lemma 2.1(iii) and (iv) then
show that \( R_0 \) and \( R_{b,*} \) are bijective, so that \( \dim \ker D = \dim X_0 \) and \( \dim \ker D^* = \dim X_{b,*} \). Using Theorem 1.4 of [12] and (6.2), we conclude
\[
\dim \ker G = \dim \ker D = \dim X_0 = \dim \ker N(b,0).
\]
Employing in addition (4.3) and (6.1), we further deduce
\[
\text{codim} \im G = \text{codim} \im D = \dim \ker D^* = \dim X_{b,*}
\]
\[
= \dim Y^+(b) = \text{codim} \im N(b,0).
\]

Theorem 1.1 has been established. \( \square \)

The image of \( G \) admits the following description in terms of trajectories \( v(\tau) = U(t,\tau)^* v(t) \), i.e., the ‘solutions of the adjoint problem’; cf. [10] or [17]. In the following proof it is again convenient to work with \( D \) instead of \( G \) since we know \( D^* \) explicitly.

**Proposition 6.1.** Let \( G \) be Fredholm on \( \mathcal{E}(\mathbb{R}) \). Then \( f \in \im G \) if and only if
\[
\int_\mathbb{R} \langle f(\sigma), v(\sigma) \rangle d\sigma = 0 \quad \forall v \in \mathcal{E}_*(\mathbb{R}) \cap \mathcal{C}_b^{w,*}(\mathbb{R}, X) \text{ with } v(\tau) = U(t,\tau)^* v(t) \quad \forall t \geq \tau,
\]
where \( \mathcal{E}_*(\mathbb{R}) = \{ v : \mathbb{R} \to X^* : v \text{ is weakly measurable, } \|v(.)\| \in L^q(\mathbb{R}), \quad q = 1 \text{ if } \mathcal{E}(\mathbb{R}) = C_0(\mathbb{R}, X), \quad \text{and } \frac{1}{p} + \frac{1}{q} = 1 \text{ if } \mathcal{E}(\mathbb{R}) = L^p(\mathbb{R}, X) \text{ with } p \in [1,\infty). \}

**Proof.** Assume that \( f \in \im G \) and \( v \in \mathcal{E}_*(\mathbb{R}) \cap \mathcal{C}_b^{w,*}(\mathbb{R}, X) \) with \( v(\tau) = U(t,\tau)^* v(t) \) for all \( t \geq \tau \). Due to Lemma 1.2, there is a function \( u \in \mathcal{E}(\mathbb{R}) \cap \mathcal{C}_0(\mathbb{R}, X) \) satisfying (1.2). So we can compute
\[
\int_\tau^t \langle f(\sigma), v(\sigma) \rangle d\sigma = \int_\tau^t \langle f(\sigma), U(t,\sigma)^* v(t) \rangle d\sigma = \int_\tau^t \langle U(t,\sigma)f(\sigma), v(t) \rangle d\sigma
\]
\[
= \langle \int_\tau^t U(t,\sigma)f(\sigma) d\sigma, v(t) \rangle = \langle U(t,\tau)u(\tau), v(t) \rangle - \langle u(t), v(t) \rangle
\]
for all \( t \geq \tau \). Letting \( \tau \to -\infty \) and \( t \to \infty \), we deduce that
\[
\int_\mathbb{R} \langle f(\sigma), v(\sigma) \rangle d\sigma = 0
\]
by means of \( u \in \mathcal{C}_0(\mathbb{R}, X) \) and \( v \in \mathcal{C}_b^{w,*}(\mathbb{R}, X) \).

Assume that \( f \in \mathcal{E}(\mathbb{R}) \) satisfies the condition in the proposition. We define the operator \( R : \mathcal{E}(\mathbb{R}) \to \mathcal{E}(\mathbb{Z}) \) by setting
\[
(Rg)_n = -\int_{n-1}^n U(n,\tau)g(\tau) d\tau \quad \text{for all } n \in \mathbb{Z}.
\]
We claim that \( Rf \in \im D \). Since \( G \) is a Fredholm operator, Theorem 1.4 in [12] shows that \( \im D \) is closed, and thus \( \im D = (\ker D^*)^\perp \). For \( \xi = (\xi_n)_{n \in \mathbb{Z}} \in \ker D^* \), we define \( v : \mathbb{R} \to X^* \) by \( v(\tau) = U(n,\tau)^* \xi_n \) for \( \tau \in (n-1, n] \) and \( n \in \mathbb{Z} \). Due to (2.5), we obtain \( v \in \mathcal{E}_*(\mathbb{R}) \cap \mathcal{C}_b^{w,*}(\mathbb{R}, X) \) and \( v(\tau) = U(t,\tau)^* v(t) \) for all \( t \geq \tau \).

Furthermore,
\[
\langle Rf, \xi \rangle = -\sum_{n \in \mathbb{Z}} \langle \int_{n-1}^n U(n,\tau)f(\tau) d\tau, \xi_n \rangle = -\sum_{n \in \mathbb{Z}} \int_{n-1}^n \langle f(\tau), U(n,\tau)^* \xi_n \rangle d\tau
\]
Lemma 2.1(i). As a result, \( \dim X \) means that the map \( u \) is easy to check that the following assertions hold. (see the introduction) in terms of the spaces \( X_n \) and \( X_{n,*} \).

Assume that the operator \( G \) is Fredholm on \( E(\mathbb{R}) \). Then the following assertions hold.

(i) (BU.1) holds if and only if \( \dim X_n \) is constant for \( n \in \mathbb{Z} \);

(ii) (BU.2) holds if and only if \( \dim X_{n,*} \) is constant for \( n \in \mathbb{Z} \);

(iii) If (BU.1) and (BU.2) hold, then we can take \( a = b = 0 \) in Theorem 1.1.

Proof. (i) Assume that (BU.1) holds. Take \( x \in X_n \) with \( U(n,m)x = 0 \) for some \( n \geq m \). Then there is a sequence \( x = (x_k)_{k \in \mathbb{Z}} \in \ker D \) such that \( x_m = x \) by (2.2).

We define the function \( u : \mathbb{R} \to X \) by \( u(t) = U(t,j)x_j \) for \( t \in [j,j+1) \) and \( j \in \mathbb{Z} \). It is easy to check that \( u \in C_0(\mathbb{R},X) \) and \( u(t) = U(t,\tau)u(\tau) \) for all \( t \geq \tau \) using (2.4).

Since \( u(n) = U(n,m)x_m = U(n,m)x = 0 \), (BU.1) shows that \( u(m) = x = 0 \). This means that the map \( U(n,m) : X_m \to X_n \) is injective, and hence it is bijective by Lemma 2.1(i). As a result, \( \dim X_m = \dim X_n \) for all \( n \geq m \).

Assume that \( \dim X_n \) is constant on \( \mathbb{Z} \). Let \( u \in C_0(\mathbb{R},X) \) be a function satisfying \( u(t) = U(t,\tau)u(\tau) \) for all \( t \geq \tau \) and \( u(\tau_0) = 0 \) for some \( \tau_0 \in \mathbb{R} \). Obviously, \( u(t) = 0 \) for all \( t \geq \tau_0 \). By Theorem 1.1, \( \mathcal{U} \) has an exponential dichotomy on \( (-\infty,a) \) for some \( a \in \mathbb{R} \). Thus, using that \( \sup_\tau \|P_\tau^{-}\| < \infty \), we can estimate

\[
\|P_\tau^{-}u(t)\| = \|U(t,\tau)P_\tau^{-}u(\tau)\| \leq Ne^{-\nu(t-\tau)}\|P_\tau^{-}u(\tau)\| \leq N'e^{-\nu(t-\tau)}\|u\|_\infty
\]

for all \( \tau \leq t \leq a \). Letting \( \tau \to -\infty \), we obtain that \( P_\tau^{-}u(t) = 0 \), i.e., \( u(t) \in X_u(t) \), for all \( t \leq a \). Then we derive the inequality

\[
\|u(t)\| = \|U_n(a,t)^{-1}u(a)\| \leq Ne^{-\nu(a-t)}\|u(a)\|
\]

for all \( t \leq a \). As a result, \( (u(n))_{n \in \mathbb{Z}} \in \ker D \) which leads to \( u(n) \in X_n \) for all \( n \in \mathbb{Z} \) (see (2.4) and (2.2)). The identity \( \dim X_n = \dim X_m \) and Lemma 2.1 then yield the invertibility of \( U(n,m) : X_m \to X_n \) for all \( n \geq m \). Thus \( u(n) = 0 \) for all \( n \in \mathbb{Z} \) since \( u(n) = 0 \) for large \( n \).

(ii) Assume that (BU.2) holds. Take \( \xi \in X_{n,*} \) with \( U(n,m)^*\xi = 0 \). Then there is a sequence \( \xi = (\xi_k)_{k \in \mathbb{Z}} \in \ker D^* \) such that \( \xi_n = \xi \) by (2.3). We define the function \( v : \mathbb{R} \to X^* \) by \( v(t) = U(j,t)^*\xi_j \) for \( t \in (j-1,j) \) and \( j \in \mathbb{Z} \). It is straightforward to see that \( v \in C_0^w(\mathbb{R},X^*) \) and \( v(\tau) = U(t,\tau)^*v(t) \) for all \( t \geq \tau \). Since \( v(m) = U(n,m)^*\xi_n = U(n,m)^*\xi = 0 \), (BU.2) yields \( v = 0 \), and thus \( \xi = 0 \).

Now Lemma 2.1(ii) implies that \( \dim X_{n,*} = \dim X_{m,*} \) for \( n \geq m \).

Assume that \( \dim X_{n,*} \) is constant on \( \mathbb{Z} \). Let \( v \in C_0^w(\mathbb{R},X) \) satisfy \( v(\tau) = U(t,\tau)^*v(t) \) for all \( t \geq \tau \) and \( v(\tau_0) = 0 \) for some \( \tau_0 \in \mathbb{R} \). Hence, \( v(\tau) = 0 \) for all \( \tau \leq \tau_0 \). Theorem 1.1 shows that \( \mathcal{U} \) has an exponential dichotomy on \([0,\infty)\). This fact, due to \( \sup_\tau \|P_\tau^{-}\| < \infty \), leads to the estimate

\[
|\langle P_\tau^+x,v(\tau)\rangle| = |\langle P_\tau^+x,U(t,\tau)^*v(t)\rangle| = |\langle U(t,\tau)P_\tau^+x,v(t)\rangle| \leq N'e^{-\nu(t-\tau)}\|v\|_\infty\|x\|
\]

proving the claim. Using [12, Lemma 6.1(iv)], we conclude that \( f \in \text{im} \, G \). □
for all \( t \geq \tau \geq b \) and \( x \in X \). Letting \( t \to \infty \), we obtain that \( \langle P^+_r x, v(\tau) \rangle = 0 \) for all \( \tau \geq b \) and all \( x \in X \). We can now conclude that

\[
\|v(\tau)\| \leq N e^{-\nu(\tau-b)}\|I - P^+_r\| \|x\| \|v(b)\|
\]

for all \( \tau \geq b \) and all \( x \in X \). Consequently, \( (v(n))_{n \in \mathbb{Z}} \in \ker D^* \) and \( v(n) \in X_{n,*} \) (see (2.5) and (2.3)). Since \( \dim X_{n,*} = \dim X_{m,*} \) for all \( n \geq m \), Lemma 2.1 implies the invertibility of \( U(n, m)^* : X_{n,*} \to X_{m,*} \) for all \( n \geq m \). So we arrive at \( v(n) = 0 \) for all \( n \in \mathbb{Z} \), and hence \( v = 0 \).

(iii) The last assertion follows from (i), (ii), and the definition of \( a \) and \( b \) given after (2.5).

We present the examples mentioned in the introduction. Observe that here \( X \) is a Hilbert space and \( U \) is generated by piecewise constant operators \( A(t) = A_+ \) for \( t \geq 0 \) and \( A(t) = A_- \) for \( t \leq 0 \).

**Example 7.2.** Let \( X = L^2(\mathbb{R}_+) \), \( f_0 = \chi_{[0,1]} \), and \( P_0 : X \to X \), \( P_0 f = \langle f, f_0 \rangle f_0 \), be the orthogonal projection onto \( \text{Span}\{f_0\} \), and set \( Q_0 = I - P_0 \). Define \( (S_1(t)f)(\tau) = e^{-t} f(t + \tau) \) for \( t, \tau \geq 0 \) and \( f \in X \), and \( S_2(t)f = e^{t} P_0 f + e^{-t} Q_0 f \) for \( t \geq 0 \) and \( f \in X \). Let \( U = \{U(t, \tau)\}_{t \geq \tau} \) be the strongly continuous, exponentially bounded evolution family on \( X \) given by

\[
U(t, \tau) = \begin{cases} S_1(t - \tau), & t \geq \tau \geq 0, \\ S_1(t)S_2(-\tau), & t \geq 0 \geq \tau, \\ S_2(t - \tau), & 0 \geq t \geq \tau. \end{cases}
\]

\( G \) denotes the generator of the associated evolution semigroup defined on \( L^2(\mathbb{R}, X) \).

We claim that \( \dim \ker G = 1 \) and that, more precisely, \( \ker G \) is the set of functions \( u \) given by \( u(t) = S_1(t)u(0) \) for \( t \geq 0 \), \( u(t) = S_2(t)u(0) \) for \( t \leq 0 \), and \( u(0) \in \text{Span}\{f_0\} \). Indeed, if \( u \in \ker G \), then Lemma 1.2 shows that \( u(t) = U(t, 0)u(0) = S_1(t)u(0) \) for all \( t \geq 0 \) and \( u(0) = U(0, t)u(t) = S_2(-t)u(t) \) for all \( t \leq 0 \). Since \( u \in L^2(\mathbb{R}, X) \), we must have \( Q_0 u(0) = 0 \). The proof of the converse inclusion is straightforward. The claim is proved.

Let \( f \in L^2(\mathbb{R}_+) \) and define \( u : \mathbb{R} \to L^2(\mathbb{R}_+) \) by

\[
u(t) = \begin{cases} -\int_{-\infty}^{t} e^{r-t} Q_0 f(r) \, dr + \int_{t}^{0} e^{t-r} P_0 f(r) \, dr, & t < 0, \\ \int_{0}^{t} S_1(t - \tau) f(\tau) \, d\tau - S_1(t)Q_0 \int_{-\infty}^{0} e^{\tau} f(\tau) \, d\tau, & t \geq 0. \end{cases}
\]

Using Lemma 1.2 we see that \( u \in \text{dom } G \) and \( Gu = f \). Therefore \( G \) is surjective and thus Fredholm.

Define \( u_0 \in \ker G \) by \( u_0(t) = e^{t} f_0 \) for \( t < 0 \) and \( u_0(t) = S_1(t)f_0 \) for \( t \geq 0 \). Then \( u_0(t) = U(t, \tau)u_0(\tau) \) for all \( t \geq \tau \). However, \( u_0(0) = f_0 \neq 0 \) and \( (u_0(2))(\tau) = e^{-2} f_0(2 + \tau) = 0 \) for \( \tau \geq 0 \). As a result, (BU.1) fails for the function \( u = u_0 \).
Example 7.3. With the notations used in Example 7.2, we define the strongly continuous evolution family $\mathcal{V} = \{V(t, \tau)\}_{t \geq \tau}$ by,

$$V(t, \tau) = \begin{cases} S_2(t - \tau), & t \geq \tau \geq 1, \\ S_2(t - 1)S_1(1 - \tau)^*, & t \geq 1 \geq \tau, \\ S_1(t - \tau)^*, & 1 \geq t \geq \tau. \end{cases}$$

Arguing as in Example 7.2, we can establish the Fredholmity of the generator of the evolution semigroup on $L^p(\mathbb{R}, X)$ associated with $\mathcal{V}$. It is clear that $\mathcal{V}$ has exponential dichotomies on $\mathbb{R}_-$ and $[1, \infty)$ with projections $P^-_t = I$ for $t \leq 0$ and $P^+_t = Q_0$ for $t \geq 1$, respectively. Looking for a contradiction, we suppose that $\mathcal{V}$ has an exponential dichotomy on $\mathbb{R}_+$. The definition of the exponential dichotomy implies that $X^+_\tau(\tau) = \{f \in L^2(\mathbb{R}_+) : V(t, \tau)f \to 0 \text{ as } t \to \infty\}$. Hence, $X^+_\tau(1) = \ker P_0$, so that $X^+_\tau(1)$ must be a (one dimensional) complement of $\ker P_0$. On the other hand, $P_0V(1, 0) = P_0S_1(1)^* = 0$ contradicting the required surjectivity of $V(1, 0) : X^+_\tau(0) \to X^+_\tau(1)$. \hfill $\diamond$

Remark 7.4. In Propositions 6.1 and 7.1 we can replace $C^{0, \ast}_w(\mathbb{R}, X)$ by its subspace $C^{0, \ast}_w(\mathbb{R}, X)$ of functions vanishing at $\pm \infty$ if $\mathcal{E}(\mathbb{R}) = C_0(\mathbb{R}, X)$ or $\mathcal{E}(\mathbb{R}) = L^p(\mathbb{R}, X)$ for $p \in (1, \infty)$. This fact follows from the proofs of these results.
